Abstract

The Role of DNA Methylation in Arthropods.

Hollie Jade Marshall.

Epigenetic mechanisms, such as DNA methylation, are poorly understood in arthropods compared to mammals and plants. Arthropods have been shown to display a variety of DNA methylation profiles across species, making them ideal for understanding the function of DNA methylation outside of a mammalian context. This thesis explores the role of DNA methylation in two arthropod species; the eusocial bumblebee, *Bombus terrestris* and the freshwater crustacean *Daphnia magna*.

Previous research has implicated DNA methylation in caste determination in some social insect species. I have found differentially methylated genes between worker castes of *B. terrestris*, some of which are involved in reproduction. However, there was no direct link with differentially expressed genes. This indicates DNA methylation does not causally affect gene expression differences between castes.

Another possible function of DNA methylation in *B. terrestris* is the regulation of imprinted genes. Imprinted genes are those which display parent-of-origin allele-specific expression. Predictions based on the kinship theory state imprinted genes should exist in *B. terrestris*. I have identified parent-of-origin expression in this species, indicating some support for the kinship theory. However, DNA methylation does not appear to be directly mediating this process.

The final chapter of this thesis identified DNA methylation changes through time in a single resurrected population of *D. magna*. A small number of genes which exhibited DNA methylation changes over time were involved in the production of males, which is usually triggered by environmental change. The data generated in this chapter will be used for novel analyses investigating the adaptive potential of DNA methylation.

This thesis has contributed new knowledge to three fields: caste determination in social insects, imprinted genes in social insects and adaptive epigenetics. Taken as a whole, the studies presented here highlight the need for functional validation and the consideration of genotype in future ecological epigenetic research.

Acknowledgements

A massive thank you to Dr. Eamonn Mallon for being the most awesome supervisor! You have taught me, not only all of the science-y things I have needed, but also so much more. I've been fighting for a career for years and seeing how you balance your career with your family, and put them first, genuinely made me re-think my priorities. Thank you so much for that. On that note, thank you for grounding me when I needed it but also thank you for letting me pursue, pretty much, whatever I wanted (including swanning off to Birmingham for over a year). Also thank you for supporting the fact I needed to work. Whilst we may never be friends (you have too many already), I hope we can be colleagues.

Thank you to Dr. Luisa Orsini for hosting me in Birmingham for the final chapter of my thesis. Thank you for all of the support you offered through out this project, especially when it was going wrong at every turn. Also thank your for securing students for me even though you were on a ‘no student year’. I also want to say how much I appreciate the extra opportunities you have given me to really make this project exciting! Finally a huge thank you for managing to wangle a short-term contract for me so I can finish the analyses on this project and hopefully produce some awesome science! It is very much appreciated (no more working at Gala Bingo for me!).

I also want to say thank you to Prof. Tom Wenseleers, without whom, the bulk of this thesis would not have been possible. Thank you for trusting me with your data and samples, I hope they lead to some great publications. Also thank you for hosting me in Leuven for a week and allowing me to stay with you and Beatrice. I hope to cross paths again in the future.

Next I want to thank Dr. Sinead Drea and Dr. Ezio Rosato for providing so much encouragement and excellent feedback during my PRP meetings. They were a pleasure rather than a chore. Also thank you to Dr. Cas Kramer for offering so many public engagement opportunities and for providing dog-related support when it was very much needed! I would also like to thank Michael Jordan for supplying excellent financial

administrative support for the conferences I organised, I will be holding all future institutions to your standard.

A big thank you to all of the members of Lab 219, especially; Dr. Zoe Lonsdale, Dr. Pshtiwan Bebane, Alun Jones, Christian Thomas and Hannah Sampson. A special thank you to Lisa Bedder for helping me with so many obscure tasks, including all of the *E. coli* help which wasn't even for our lab. Another special thank you to Dr. Ben Hunt for helping tighten the differential methylation pipeline and for providing a listening ear. A final big thank you to Boris Berkhout for being an awesome friend (and tidy house-mate). I appreciate all of the statistical help and hopefully our labs will collaborate one day in the future.

Last, but certainly not least, I want to thank Mike. You have put up with so much from me over the last few years. You have; scarified holidays away, helped with my code, read drafts of my work, supported me emotionally and financially, changed your lifestyle to fit in around all of my jobs and definitely taken more than your share of the dog-related chores. You've even agreed to up-root your life to move to Scotland with me! I genuinely couldn't have asked for a better partner throughout all of this, thank you.

Collaborative Work Statement

Chapter 2: Methylation and gene expression differences between reproductive castes of bumblebee workers.

Dr. Eamonn Mallon conceived the study. Dr. Zoë Lonsdale and I carried out the animal husbandry and lab work. I conducted all bioinformatic analyses.

Chapter 3: Allele-specific methylation and gene expression in reproductive and sterile bumblebee workers.

Dr. Eamonn Mallon conceived the study. Dr. Zoë Lonsdale and I carried out the animal husbandry and lab work. I conducted all bioinformatic analyses.

Chapter 4: Reciprocal crosses and RNA-seq to explore genomic imprinting in the bumblebee, *Bombus terrestris*.

Professor Tom Wenseleers and Dr. Eamonn Mallon conceived the study. The reciprocal crosses were carried out by Biobest (Westerlo, Belgium) under supervision of Professor Felix Wäckers. Dr. Jelle van Zweden and Kristof Benaets carried out the behavioural observations and the lab work. I conducted all bioinformatic analyses.

Chapter 5: Reciprocal crosses to identify parent-of-origin methylation in the bumblebee, *Bombus terrestris*.

Dr. Eamonn Mallon, Professor Tom Wenseleers and I conceived the study. The reciprocal crosses were carried out by Biobest (Westerlo, Belgium) under supervision Professor Felix Wäckers. Dr. Jelle van Zweden and Kristof Benaets carried out the behavioural observations. I carried out the lab work and all bioinformatic analyses.

Chapter 6: Variation of methylation in naturally occurring temporal populations of the water flea, *Daphnia magna*, to environmental stressors.

Dr. Luisa Orsini and I conceived the study, with input from Dr. Eamonn Mallon and Dr. Leda Mirbahai. I carried out all animal husbandry, lab work and bioinformatic analyses.

Chapter 1

Introduction

1.1 Epigenetic mechanisms

Epigenetics refers to changes in gene expression which are not a product of the underlying genetic code. Epigenetic changes can be both inter-generational and trans-generational (Burggren and Crews, 2014). To date the vast majority of epigenetic research has been conducted in relation to disease and mechanistic understanding in humans (Feil and Fraga, 2012, Fig. 1.1). However, recent reviews and special issues of *Molecular Ecology* and *Heredity* have called for a greater understanding of the function of epigenetics in ecology and evolution (Verhoeven *et al.*, 2016; Burggren, 2016; Lind and Spagopoulou, 2018).

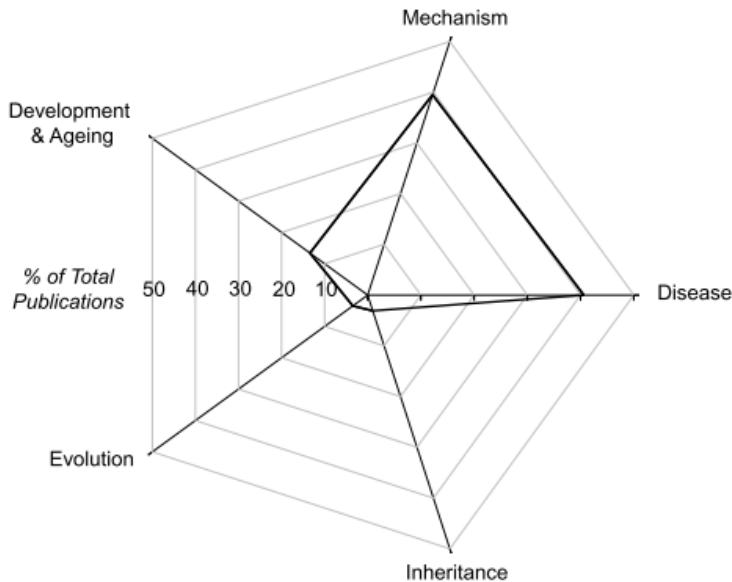

Figure 1.1: Radar diagram showing the percentage of publications in 2016 which refer to epigenetics within a particular research area, figure adapted from Burggren (2016).

Epigenetic mechanisms include: histone modifications, non-coding RNAs and DNA methylation. Histone modifications refer to chemical changes, such as: acetylation, phosphorylation and methylation, which occur on the amino (N)-terminal tails of histones (Bannister and Kouzarides, 2011). Modifications of histones can result in euchromatin, where the chromatin forms an open structure, or heterochromatin where the chromatin is highly condensed, making genes inaccessible and hence decreasing gene expression (Bannister and Kouzarides, 2011). Non-coding RNAs (ncRNAs) are RNA molecules which do not produce a protein, they can affect gene expression via multiple mechanisms, including; RNA-interference and via direction of chromatin-modifying enzymes (Glastad *et al.*, 2015). Whilst more is being understood about these mechanisms, it is DNA methylation which is currently the most studied epigenetic mark (Vogt, 2017).

DNA methylation is the addition of a methyl group to a cytosine nucleotide at the 5' carbon atom. In mammals, methylation primarily occurs in a CpG context (CpG referring to a cytosine base immediately followed by a guanine base), the percentage of CpGs methylated is usually over 70%, with methylation serving to repress gene expression when occurring in promoter regions (Feng *et al.*, 2010). DNA methylation is also observed in other genomic contexts, with centromere methylation thought to be involved in genome stability and the repression of transposable elements (Jones, 2012). Gene body methylation, in mammals, is usually tissue specific and has been linked with cancer (Jones, 2012). DNA methylation is also known to undergo global erasure and re-establishment during embryo development. However, some sites maintain their methylation status, such as those associated with imprinted genes (Messerschmidt *et al.*, 2014, see section 1.3). Whilst much is known about mammalian DNA methylation, and also DNA methylation in plants (reviewed in Zhang *et al.*, 2018), comparatively little is known about the function of DNA methylation in other species groups.

1.1.1 Arthropod DNA methylation

Arthropods are the most species diverse animal phylum and yet little is known about the overall function of DNA methylation within this group (Thomas *et al.*, 2018). Thomas

et al. (2018) recently searched for signals of DNA methylation in 76 arthropod species. They characterised observed/expected CpG content through out each genome. As DNA methylation causes spontaneous deamination of cytosine nucleotides, a lower than expected CpG density in a given genomic region indicates the presence of DNA methylation. Holometabolous insects tend to show higher CpG observed/expected frequencies indicating lower levels of genome DNA methylation, compared to hemimetabolous insects and non-insect arthropods (Bewick *et al.*, 2016; Thomas *et al.*, 2018; Provataris *et al.*, 2018). Thomas *et al.* (2018) additionally found DNA methylation shows different profiles across arthropod species: holometabolous insects appear to have DNA methylation enriched in exons, Coleoptera and Diptera appear to show very little to no DNA methylation and many other species show methylation enriched in both exons and introns. The variety of methylation profiles across arthropods implies variable functions, making arthropods ideal models for investigating the role of DNA methylation in non-mammalian animals.

Observed/expected CpG density is only a proxy for DNA methylation. However, DNA methylation has been directly identified in species from all four currently extant sub-phylum of Arthropoda: Hexapoda, Chelicerata, Myriapoda and Crustacea, with insects being explored to the greatest extent (Vogt, 2017). DNA methylation has various proposed roles within arthropods, including: polyphenism in insects, speciation in crustaceans and adaptation in arachnids (Vogt, 2017; Liu *et al.*, 2019). Polyphenisms are an extreme forms of phenotypic plasticity, where more than one distinct phenotype is produced by the same genotype (Colgan *et al.*, 2011). DNA methylation differences have been associated with insect polyphenisms, such as: social insect castes (Lyko *et al.*, 2010; Bonasio *et al.*, 2012) and gregarious and solitary locusts (Falckenhayn *et al.*, 2013). Large differences in genome-wide methylation have also been observed between two recently diverged cray-fish species, *Procambarus virginalis* and *Procambarus fallax* (Gatzmann *et al.*, 2018), suggesting a potential role for DNA methylation in speciation. Finally DNA methylation has been hypothesised to play a role in the adaptive capability of species with low genetic diversity, such as the social spider, *Stegodyphus dumicola* (Liu *et al.*, 2019).

This thesis attempts to further explore the role of DNA methylation in a hexapod

and crustacean species, the primitively eusocial insect, *Bombus terrestris* and the parthenogenetic crustacean, *Daphnia magna*. To do this I will use the current gold standard for DNA methylation identification, whole-genome bisulfite sequencing. This method involves treating genomic DNA with bisulfite. Bisulfite treatment causes deamination of any unmethylated cytosine, resulting in a uracil base, this is then transcribed into a thymine during PCR (Fig. 1.2), any remaining cytosine nucleotides are therefore known to be methylated. The treated DNA can then be sequenced using next-generation sequencing technologies and advances in bioinformatic pipelines allow methylated bases to be identified with confidence.

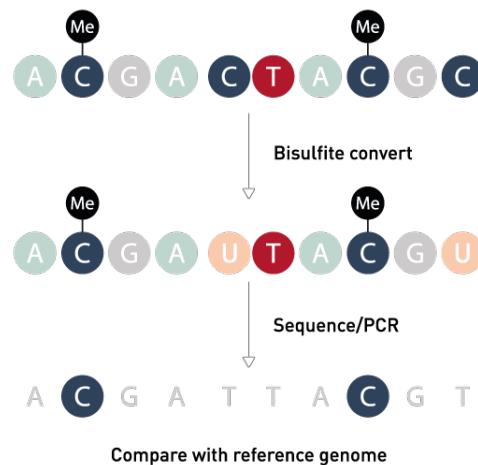

Figure 1.2: The bisulfite chemical causes deamination of unmethylated cytosine nucleotides, forming uracil. The uracil is then translated into thymine during the PCR process. Final sequencing data contains only cytosines which were methylated in the original sample. Image adapted from: <https://www.diagenode.com/en/categories/bisulfite-conversion>.

1.1.2 Thesis rationale

The following sections provide more specific background for the three projects of this thesis:

- DNA methylation as a mechanism of caste-determination in the social insect *Bombus terrestris* (Section 1.2, Chapter 2)
- DNA methylation as a mechanism of imprinting genes in the social insect *Bombus*

terrestris (Section 1.3, Chapters 3, 4 and 5)

- DNA methylation as an adaptive mechanism in the crustacean *Daphnia magna* (Section 1.4, Chapter 6).

Whilst I provide a comprehensive introduction, each chapter is written in a ‘stand-alone’ manuscript style in order to ease later publication. This means there will be some repetition between the main introduction and the individual chapter introductions.

1.2 Methylation and social-insect caste determination

1.2.1 Caste determination

Phenotypic plasticity is the production of multiple phenotypes from a single genome. It plays a crucial role in the adaptive capabilities of species (Chevin *et al.*, 2010) and is notably observed in social insects. Social insects exhibit, sometimes extreme, morphological and behavioural differences between individuals of a single colony, known as castes. The mechanisms by which species develop differences between castes are diverse; some species use only environmental cues whilst others rely only on inherited changes, with some species falling somewhere in between these two extremes (Matsuura *et al.*, 2018).

Genetic caste determination has been observed in species of *Cataglyphis* and *Pogonomyrmex* ant, this occurs when two distinct genetic lines cross to produce sterile workers, whereas inbreeding within a single line produces reproductive queens (Leniaud *et al.*, 2012; Eyer *et al.*, 2013; Mott *et al.*, 2015). Kuhn *et al.* (2018) have shown one of these species, *Cataglyphis mauritanica*, is capable of producing single-lineage workers as well as hybrid reproductive queens in lab conditions, although the latter was in response to juvenile hormone treatment. This shows that whilst this species exhibits genetic caste-determination, it still maintains some level of phenotypic plasticity within its genome.

Many other species utilise cues from the environment in order to determine caste. For example, the presence of queen pheromone, as well as queen-worker interactions, in *Bombus* species have been shown to reduce the reproductive development of workers (Padilla *et al.*, 2016). In a species of primitively eusocial paper wasp, *Polistes jokahamae*, exposure to short-photoperiods was found to cause a higher production of new queens (Yoshimura and Yamada, 2018). Additionally, nutritional content and food availability have been shown to influence caste determination, for example when honeybee larvae are fed royal jelly they develop into queens rather than workers. (Haydak, 1943).

With the production of new molecular techniques it has recently become possible to begin to explore the epigenetic mechanisms which may underlie caste determination in response to environmental factors. Various epigenetic differences have now been associated with different castes in various species. For example, variation in microRNA expression levels has been identified in both honeybee (Ashby *et al.*, 2016) and bumblebee (Collins *et al.*, 2017) castes. Additionally, histone acetylation has been shown to alter the behaviour of major workers of the ant species *Camponotus floridanus*, making them more similar to the behaviour of minor workers (Simola *et al.*, 2016). However, the most active research in this area has been focused on DNA methylation (Glastad *et al.*, 2015).

1.2.2 Social-insect methylation

DNA methylation has been associated with the switching of worker castes in honeybees (Herb *et al.*, 2012). A major finding was that silencing of the *Dnmt3* gene (involved in methylation establishment) in larvae produced queens rather than workers (Kucharski *et al.*, 2008). DNA methylation has also been linked with alternative splicing differences between castes in two ant species (Bonasio *et al.*, 2012) and is thought to be involved in caste determination in *Copidosoma koehleri*, a species of primitively social wasp (Shaham *et al.*, 2016).

However, it is clear DNA methylation is not a conserved mechanism in Hymenoptera for caste differentiation. No association between caste and methylation has been found

in a number of ant and wasp species (Patalano *et al.*, 2015; Standage *et al.*, 2016). Additionally, the statistical methods of previous next generation sequencing analyses on social insect methylation have been brought into question (Libbrecht *et al.*, 2016).

Whilst DNA methylation differences have been found in some species, the actual role of DNA methylation in caste determination is still unknown. Cardoso-Júnior *et al.* (2017) propose a combined genetic-epigenetic mechanism of caste determination in the stingless bee, *Melipona scutellaris* (Fig. 1.3). Previous work found evidence for a genetic caste-determination system governed by two separate genes (Corona *et al.*, 2016), whereas Cardoso-Júnior *et al.* (2017) found DNA methylation and histone modifications linked to different castes which may be influenced by larval nutrition. This work shows the importance of understanding whether DNA methylation has a causal relationship with changes in gene expression or whether it is a consequence of caste-differences.

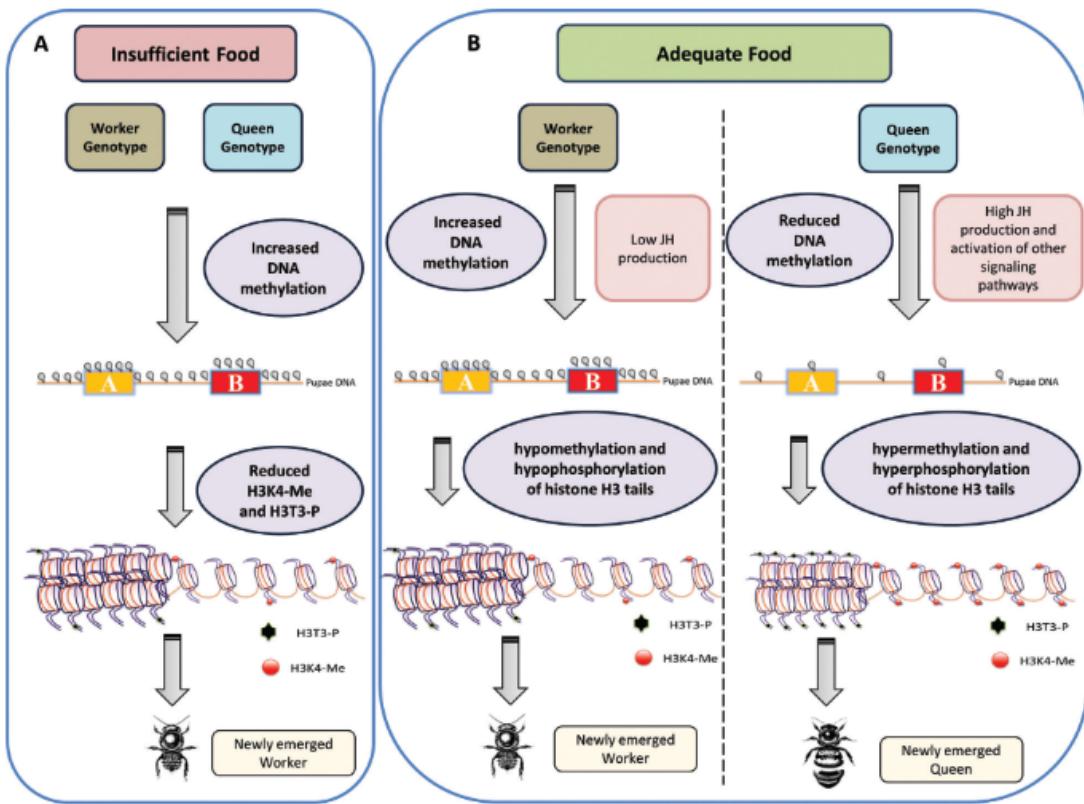

Figure 1.3: (A) Cardoso-Júnior *et al.* (2017) propose low nutrient consumption in the stingless bee, *Melipona scutellaris*, leads to increased DNA methylation which in turn reduces histone modifications, leading to the production of workers, regardless of the underlying genotype. (B) under good nutrient conditions, a queen-genotype is needed to create a decrease in DNA methylation leading to an increase in histone modifications which enable the queen phenotype. Image from Cardoso-Júnior *et al.* (2017).

1.2.3 Bumblebees as a model system

Bumblebees provide an ideal system to further investigate the relationship between gene expression and methylation in social insect caste determination. Firstly, bumblebees are important both economically and environmentally as a pollinator species. They are generalist pollinators and are given keystone species status in some ecosystems (Woodard *et al.*, 2015). *B. terrestris* colonies are annual and are founded by a singly-mated queen in early spring (Fig. 1.4), she will lay diploid eggs resulting in female workers and later switch to male haploid eggs, known as the switching point (Bloch, 1999). A competition phase then occurs between queens and workers, where some workers will become reproductive and produce their own haploid sons (Alaux

et al., 2006), this results in distinct reproductive worker phenotypes within the colony. Throughout this thesis I will refer to individuals with a reproductive or sterile phenotype as distinct worker castes. This deviates from the traditional definition of a caste as these phenotypes are not fixed during development. Instead, some individual workers develop the reproductive phenotype later in life in response to environmental cues.

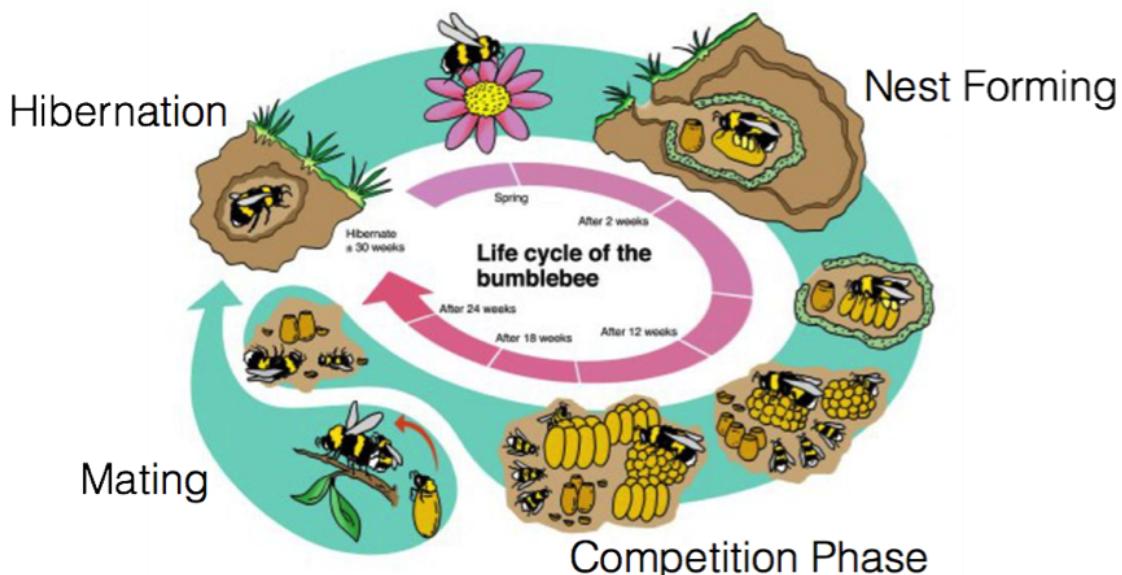

Figure 1.4: Bumblebee life cycle: nests are formed from mated queens emerging from hibernation, they lay female worker destined eggs, once hatched the workers then aid in foraging and brood care. During the competition phase some workers develop functioning ovaries and lay haploid male eggs, the queen will also begin to lay haploid male eggs and produce female queen destined larvae. Males and new queens will leave the nest and new queens will be singly mated (i.e. by only one male) before hibernating. Figure adapted from: <https://www.natupol.com/why-natupol/our-best-bumblebees/longevity/>.

B. terrestris also has a sequenced genome, the genome size is small, 249Mb, allowing large computational analyses to be run in relatively short time periods (Sadd *et al.*, 2015). Sequencing of the genome revealed a methylation system: including two copies of the *DNMT3* gene and a copy of *DNMT1* (needed for the methylation of genes), a copy of *PIWI* (involved in methylation targeting) and a copy of *TET* (involved in methylation removal). Overall CpG methylation levels, are relatively low compared to mammals, with only 0.5-0.6% of all CpG's being methylated (Sadd *et al.*, 2015). Additionally, genes involved in DNA methylation have also been shown to have varying expression levels between queens, workers and drones (Li *et al.*, 2018) and experimental changes

in methylation in *B. terrestris* workers has been shown to alter levels of reproductive behaviour (Amarasinghe *et al.*, 2014). These studies hint to the possibility that DNA methylation may play a role in caste determination in *B. terrestris*.

1.2.4 Project aims

The first results chapter of this thesis, Chapter 2, aims to determine if there is a direct association between reproductive caste determination and DNA methylation in *B. terrestris*. As part of this project, this chapter also aims to characterise the *B. terrestris* methylome and determine the relationship between DNA methylation, gene expression and alternative splicing in this species. If differentially methylated genes are identified between castes which are enriched for differentially expressed or alternatively spliced genes, involved in reproductive processes, this would indicate the potential of DNA methylation as a mechanism of caste determination in *B. terrestris*.

1.3 Genomic imprinting in social insects

1.3.1 Genomic imprinting

Genomic imprinting is the expression of only one allele at a given locus, in a diploid organism, with expression being dependent upon the parental origin of the allele (Barlow and Bartolomei, 2014). Genomic imprinting was first discovered in the 1980's. Mouse embryos formed from a single parent, whilst still having a diploid genome, did not develop normally. Chromosomes from both a male and female parent were needed (McGrath and Solter, 1984). Imprinted genes have primarily been described in placental mammals and flowering plants (Barlow and Bartolomei, 2014). However, the term 'imprinting' was first used to describe elimination of specific parental chromosomes in a species of fly, *Sciara impatiens* (Crouse *et al.*, 1971).

Whilst the mechanisms of chromosomal imprinting in insects remain unknown, DNA methylation has been found to be the primary epigenetic imprinting mark in mammals.

DNA methylation controls gene expression by occurring in imprinting control regions (ICRs) (Delaval and Feil, 2004). Hypermethylation of ICRs can result in either allelic silencing or allelic expression, depending on the mechanism of action (Drewell *et al.*, 2012; Barlow, 2011).

Imprinted genes may be individually silenced by DNA methylation, this occurs when DNA methylation blocks transcription factors from binding to the gene promotor (Drewell *et al.*, 2012). It is also thought DNA methylation may signal the recruitment of histone modifications which result in heterochromatin formation, silencing the expression of all alleles within a region (Barlow, 2011). DNA methylation can also signal the expression of imprinted genes by silencing an ‘imprinting control element’, such as a long non-coding RNA, which, when expressed, would cause transcriptional silencing of nearby genes (Barlow, 2011). It is also worth noting that most of the currently identified imprinted genes in mammals have some association with DNA methylation. However, there are cases where imprinting has been linked solely with a particular histone modification (Inoue *et al.*, 2017).

1.3.2 Theories of genomic imprinting

Genomic imprinting presents an evolutionary paradox. In diploid organisms having two copies of a particular gene means that if one allele carries a harmful mutation, the other allele can compensate, so function is not lost. However, the expression of only a single allele means this evolutionary advantage is removed (Amarasinghe *et al.*, 2014). Many theories therefore attempt to explain the presence of genomic imprinting, the three most widely accepted theories are: the sexual antagonism theory (Day and Bonduriansky, 2004), the maternal-offspring co-adaptation theory (Wolf and Hager, 2006) and the kinship theory (Haig, 2000).

The sexual antagonism theory is based on gender specific selection pressures, if males and females are under different selection pressures then alleles will have different frequencies in the eggs and sperm, meaning different frequencies of matrigenes (genes from the mother) and patrigenes (genes from the father) in the offspring (Patten *et al.*, 2014). For example if sexual selection favours a particular trait that is only expressed in males

then the maternal allele should be imprinted (silenced in this case) making the phenotype of the male offspring more heritable (Day and Bonduriansky, 2004). However, this theory fails to explain the expression of matrigenes in the testes of mammalian males and the expression of patrigenes in the mammary-glands of females (Patten *et al.*, 2014).

Wolf and Hager (2006) proposed the maternal-offspring co-adaptation theory. This theory predicts imprinting occurs because each allele in the offspring provides a different level of ‘fitness interaction’ with the mother (Patten *et al.*, 2014). For example, if fitness is increased when there is a high similarity between the mother’s genetic make up and the offspring’s, then it can be expected the maternal alleles are expressed and the paternal alleles are silenced (Patten *et al.*, 2014). Wolf and Hager (2006) acknowledge the most widely accepted theory for genomic imprinting is that of conflict between maternal and paternal alleles over maternal investment, this principle is the basis of Haig’s kinship theory (Haig, 2000).

1.3.3 Haig’s kinship theory

Haig’s kinship theory is currently the most widely accepted theory for genomic imprinting (Spencer and Clark, 2014). This theory was originally developed in the late 1990’s, Haig (1996) suggests that in a polyandrous mating system the genetic relatedness of the offspring is higher for maternally inherited alleles than it is for paternally inherited alleles, this is because offspring may have different fathers. Therefore selection should act on paternally inherited alleles to increase individual resource allocation from the mother, thereby increasing paternal inclusive fitness, whereas maternal alleles should be selected to favour equal resource distribution amongst offspring to maximise maternal inclusive fitness (Wilkins and Haig, 2003). This theory would explain why, in mammals, imprinted genes which express the maternal allele favour a decrease in individual size and imprinted genes which express the paternal allele favour an increase in size (Queller, 2003). This theory also fits with genomic imprinting being prevalent in mammals and flowering plants where the mother provides resources (Queller, 2003). This theory also extends beyond the polyandrous mating system and is thought to be applicable in cases where males provide the offspring care (reversing the theory’s

predictions) and in haplodiploid insect systems (Haig, 2000; Queller, 2003).

1.3.4 Social insects as an independent test

Eusocial hymenoptera provide an ideal system to study Haig's kinship theory. For example; colonies of social bees consist of diploid females (queens and workers) and haploid males created from unfertilised eggs. This haplodiploidy results in workers which all share the full paternal genome, when queens are singly mated. In this scenario the kinship theory (Haig, 2000) predicts patrigenes should be under stronger selection for general care-giving compared to matrigenes. However, when queens mate with multiple males, workers are more likely to have higher maternally derived relatedness and the predictions reverse (Queller, 2003).

There has been a recent increase in evidence for the predictions of genomic imprinting in social insects. Firstly, the presence of functional DNA methylation systems (the main mechanism of imprinting in mammals and flowering plants) have been found in multiple species (Glastad *et al.*, 2015). DNA methylation has been traced to the gametes in honeybees and Drewell *et al.* (2014) suggest some of the patterns seen indicate parent specific methylation patterns. Oldroyd *et al.* (2014) found a parent-of-origin effect on ovary size in honeybees concurrent with the kinship theory's predictions. Additionally, paternal effects were observed in care-giving associated behaviours and in sex allocation of offspring in the Argentine ant, *Linepithema humile* (Libbrecht and Keller, 2012; Libbrecht *et al.*, 2011).

More recently, reciprocal crosses and next generation sequencing technologies have been used to identify genes with parent-of-origin expression patterns in honeybees. Kocher *et al.* (2015) and Galbraith *et al.* (2016b) both used RNA-Seq to study parent-of-origin gene expression in hybrid crosses of honeybee sub-species. Kocher *et al.* (2015) found a matrigenic bias in gene expression. However, it was later shown that sub-species incompatibility effects influenced the results obtained (Gibson *et al.*, 2015). Showing some support for the kinship theory, Galbraith *et al.* (2016b) found a greater patrigenic expression in reproductive workers compared to sterile workers, with increased patrigenic expression in the reproductive tissues. However, this study is limited to only one

species and tests only one prediction from the many predictions made in Queller (2003) for how matrigenic/patrigenic expression bias may play a role in social insect colonies.

1.3.5 Bumblebees as a model system

Bumblebees provide an ideal model to further test Haig's kinship theory in social insects. As discussed in section 1.2.3, *Bombus terrestris* can be easily reared in the lab and has a small sequenced genome. Additionally, this species has a functional DNA methylation system which may be involved in reproductive caste determination (Amarasinghe *et al.*, 2014), meaning the epigenetic tools which drive imprinting in mammals and plants are present.

Additionally, previous research has identified both allele-specific expression and allele-specific methylation in *B. terrestris*, hinting to the existence of imprinted genes. Using a candidate gene approach, previous research identified allele-specific expression in a gene (ecdysone 20-monoxygenase-like) related to worker reproductive behaviour in *B. terrestris* (Amarasinghe *et al.*, 2015). Additional research has since used RNA-seq data to identify >500 loci showing allele-specific expression throughout the *B. terrestris* genome (Lonsdale *et al.*, 2017). This same study also identified 19 genes displaying allele-specific expression and allele-specific methylation, although this was in a single individual (Lonsdale *et al.*, 2017).

Finally, bumblebees provide a robust test for the kinship theory as predictions regarding worker reproduction are the opposite of those for the honeybee, which previous research has focused on (Galbraith *et al.*, 2016b; Kocher *et al.*, 2015). In bumblebee colonies under queen-right conditions, Queller (2003) predicts patrigenes in any given worker will be selected to favour worker reproduction as there is a 50% chance they will occur in any worker offspring, but a 0% chance they will occur in the queen's male offspring (Fig. 1.5a). Patrigenes in workers should therefore be selected to increase egg laying at the cost of rearing fewer brothers. Matrigenes should be selected to regulate worker reproduction when it is associated with high costs to brothers as these genes are less likely to occur in nephews than they are in brothers.

Under queen-less conditions the predictions are reversed. Matrigenes should now be selected to favour individual worker reproduction as there is a higher likelihood they are present in the individual worker's offspring than in her nephews (Fig. 1.5b). Patrigenes should now not experience selective pressure for reproductive behaviour as it is equally likely they will occur in the offspring of an individual worker or her nephews, meaning sterility and nursing behaviour are just as beneficial as reproductive behaviour.

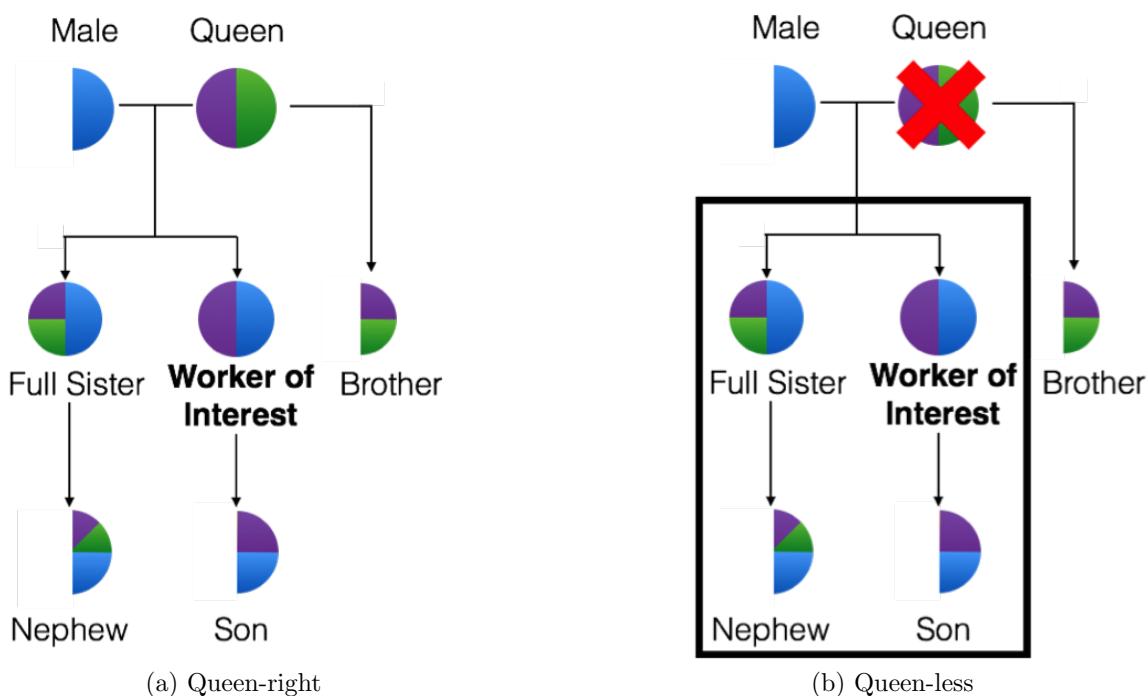

Figure 1.5: Schematic adapted from Drewell *et al.* (2012) showing the inheritance probabilities of the maternal and paternal genome in various offspring in singly-mated bumblebee colonies. (a) Under a queen-right scenario patrigenes should be under selection pressures to increase worker reproduction at the cost of rearing brothers. (b) Under queen-less conditions matrigenes should now experience higher selection pressures for worker reproduction compared to nursing behaviour for nephews.

1.3.6 Project aims

Building on previous research, Chapter 3 in this thesis aims to identify allele-specific expression and allele-specific methylation in both reproductive and sterile *B. terrestris* workers. If genomic imprinting plays a role in worker reproductive behaviour in *B. terrestris*, genes showing allele-specific expression will be enriched for reproductive pro-

cesses. Additionally, if DNA methylation acts as an imprinting mark in *B. terrestris*, a direct association between allele-specific expression and allele-specific methylation will be found.

Chapter 4 then aims to test Haig's kinship theory of genomic imprinting by utilising reciprocal crosses of two *B. terrestris* sub-species, *B. t. audax* and *B. t. dalmatinus*. RNA-seq from reproductive and sterile workers, collected under queen-less conditions, should show higher matrigenic expression bias in genes displaying parent-of-origin allele-specific expression. Additionally, if genomic imprinting plays a direct role in reproductive caste determination, differentially expressed genes between castes will be enriched for genes that also display parent-of-origin allele-specific expression.

Finally, Chapter 5 aims to identify parent-of-origin methylation in reproductive workers, collected under queen-less conditions, from independent reciprocal crosses of *B. t. audax* and *B. t. dalmatinus*. If DNA methylation is an epigenetic imprinting mark in *B. terrestris* then parent-of-origin allele-specific methylation will be identified in numerous genes. Additionally, if DNA methylation directly affects parent-of-origin allele-specific expression in a consistent manner, then there may be overlap with the genes identified in Chapter 4.

1.4 Adaptive methylation in natural populations

Adaptive epigenetics is a relatively new field of research (Verhoeven *et al.*, 2016). When there is limited genetic diversity within a population, it has been suggested selection can act upon phenotypes which are a result of the underlying epigenetic code (Lind and Spagopoulou, 2018). Additionally, the rate of spontaneous epimutations has been estimated to be higher than that of genetic mutations providing increased variation which may enable adaptation (van der Graaf *et al.*, 2015). Epigenetic adaptations can come in the form of: short term temporary responses (epigenetic plasticity), long term permanent responses and heritable permanent responses (epigenetic adaptation) (Weyrich *et al.*, 2015). Research has focused on DNA methylation as it has been suggested that it can provide an additional heritable layer of information upon which

selection and adaptive evolution can act (Richards *et al.*, 2010).

Epigenetic mechanisms underlie various types of phenotypic plasticity, with many studies recording changes in DNA methylation in response to environmental stressors. These studies span a variety of species, for example: *Arabidopsis thaliana* (Dowen *et al.*, 2012), stickleback (Artemov *et al.*, 2017) and corals (Dixon *et al.*, 2018). Additionally, permanent epigenetic differences between locally adapted populations have been identified in: *A. thaliana* (Kooke and Keurentjes, 2015), bats (Liu *et al.*, 2015), oak trees (Platt *et al.*, 2015), chickens (Zhang *et al.*, 2017) and stickleback (Heckwolf *et al.*, 2019).

As well as environmentally induced changes in DNA methylation and stable epimutations contributing to adaptive phenotypes, it is also thought changes in DNA methylation in response to the environment may contribute to later genetic adaptation. The presence of DNA methylation has been associated with an increased rate of C/T SNP substitutions which occur through spontaneous deamination (Flores *et al.*, 2013). Flores *et al.* (2013) propose environmentally induced DNA methylation, that is beneficial in terms of survival and reproduction, will remain present in individuals when the environment is constant. This will lead to an increase in C/T mutations which may facilitate maintenance of the phenotype produced originally by the DNA methylation. However, this particular theory is difficult to test given the long-term nature of the study needed.

Many of the studies mentioned above either focus on a single experimental generation or utilise the ‘space-for-time’ method, whereby spatially separated populations under different environmental conditions are used as a proxy to try to understand how species adapt to environmental change. However, it is difficult to take all naturally occurring variables into account with this method and so observing adaptation in a single population over time is preferable. Observing adaptation through time often involves long-term studies across multiple generations, of which there are few, see Grant and Grant (2002) as a rare example. Resurrection ecology provides a means of observing temporal adaptation within the same population by utilising dormant life stages such as seeds or eggs from dated sediment cores (Kerfoot *et al.*, 1999), avoiding the long-term nature of such studies.

1.4.1 *Daphnia* as a model system

The freshwater crustacean, *Daphnia magna*, provides an ideal model to study the adaptive ability of DNA methylation in arthropods. It produces a dormant life stage which can be hatched after hundreds of years of dormancy, with the oldest resurrected individual dated to around 700 years old (Frisch *et al.*, 2014), this means the same population can be directly studied through evolutionary time. Additionally, *D. magna* reproduces clonally during its life cycle (Fig. 1.6) and it is easily cultured in the lab, allowing a resurrected ‘genotype’ to be maintained for many generations. Additionally, each resurrected individual is sexually produced and so provides a unique genetic line (Fig. 1.6). Previous research has found resurrected individuals provide a genetically representative sample of temporal populations obtained from dated sediment cores (Orsini *et al.*, 2016).

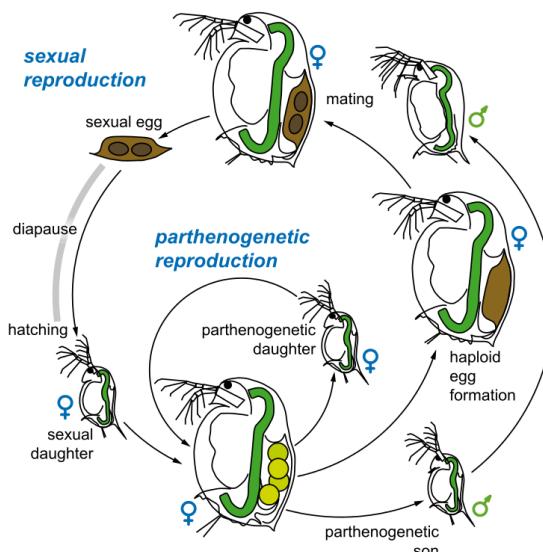

Figure 1.6: *Daphnia* life cycle. *Daphnia* exhibit cyclic parthenogenesis. Under stable environmental conditions females reproduce clonally. Under stressful conditions they produce males and sexual haploid eggs which are fertilised to produce a ‘resting’ life stage. These sexual eggs will eventually hatch into a genetically distinct female. Image credit: Dita Vizoso, source: http://scienceresourcebox.co.nz/blog/post&post_id=24.

D. magna also has a fully functional DNA methylation system, with methylation primarily found in gene bodies and associated with higher gene expression (Kvist *et al.*, 2018). Additionally, single-site CpG methylation levels have been reported between

0.7-1.7% (Kvist *et al.*, 2018; Hearn *et al.*, 2019), which is also similar to some insect species (Bewick *et al.*, 2016), such as *Bombus terrestris* which shows around 0.2% CpG methylation (Chapter 2).

The methylome of *D. magna* has been shown to be responsive to changes in environmental conditions. For example: sex-determination and sexual reproduction are the product of epigenetic changes caused by stressful conditions (Harris *et al.*, 2012), the presence of predators induces epigenetic changes which alter the phenotype (Asselman *et al.*, 2015) and calorie restriction alters genome-wide CpG methylation (Hearn *et al.*, 2019). Transgenerational effects on DNA methylation induced by chemical exposure (Vandegehuchte *et al.*, 2010) and salt stress (Jeremias *et al.*, 2018) have also been documented. Jeremias *et al.* (2018) found that changes in methylation after salt stress persisted until the F3 generation, indicating adaptive epigenetic heritability. When assessing the heritability of DNA methylation changes, that are environmentally induced, it is vital that individuals are examined at least three generations after the removal of the environment in question. This is because the gametes which generate the F2 generation would have been exposed to the test environment (Fig. 1.7).

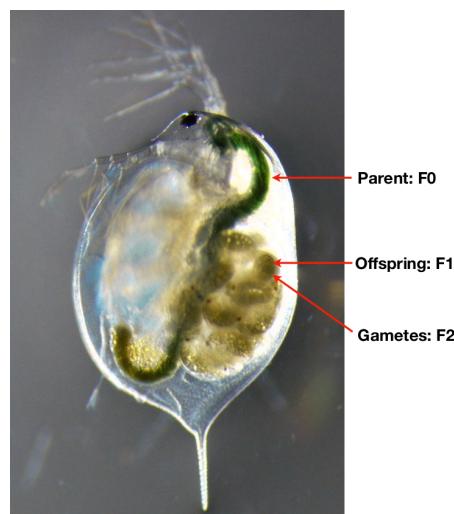

Figure 1.7: Adult female *Daphnia magna* with neonates inside the brood pouch. Exposure of the generation would also result in exposure up to the F2 generation via the germline of the F1.

1.4.2 Project aims

The final results chapter of this thesis, Chapter 6, aims to use resurrection ecology to assess changes in DNA methylation in a naturally occurring temporal population of *Daphnia magna*. The population chosen underwent historical eutrophication and pesticide exposure during two separate time periods. The identification of stable DNA methylation differences in historically exposed sub-populations compared to historically unexposed sub-populations would indicate environmentally induced heritable DNA methylation changes exist in *D. magna*. These differences could indicate an adaptive role for DNA methylation in this species.

Chapter 2

Methylation and gene expression differences between reproductive castes of bumblebee workers.

Hollie Marshall, Zoë Lonsdale and Eamonn Mallon.

Work from this chapter is published in:

Marshall, H., Lonsdale, Z.N. and Mallon, E.B. (2019). Methylation and gene expression differences between reproductive castes of bumblebee workers. *Evolution Letters*. DOI:

<https://doi.org/10.1002/evl3.129>

Appendix A.

2.1 Abstract

Phenotypic plasticity is the production of multiple phenotypes from a single genome and is notably observed in social insects. Multiple epigenetic mechanisms have been associated with social insect plasticity, with DNA methylation being explored to the greatest extent. DNA methylation is thought to play a role in caste determination in *Apis mellifera*, and other social insects, but there is limited knowledge on its role in other bee species. In this study, I analysed whole genome bisulfite sequencing and RNA-seq data sets from head tissue of reproductive and sterile castes of the eusocial bumblebee *Bombus terrestris*. I found that genome-wide methylation in *B. terrestris* is similar to other holometabolous insects and does not differ between reproductive castes. I also found differentially methylated genes between castes, which are enriched for multiple biological processes including reproduction. However, I found no relationship between differential methylation and differential gene expression or differential exon usage between castes. My results also indicate high intercolony variation in methylation. These findings suggest that methylation is associated with caste differences but may serve an alternate function, other than direct caste determination in this species. This study provides the first insights into the nature of a bumblebee caste-specific methylome as well as its interaction with gene expression and caste-specific alternative splicing, providing greater understanding of the role of methylation in phenotypic plasticity within social bee species. Future experimental work is needed to determine the function of methylation and other epigenetic mechanisms in insects.

2.2 Introduction

Phenotypic plasticity is the production of multiple phenotypes from a single genome. It plays a crucial role in the adaptive capabilities of species (Chevin *et al.*, 2010) and is notably observed in social insects. Social insects exhibit sometimes extreme morphological and behavioural differences within a single colony, known as castes. The mechanisms by which species develop differences between castes are diverse; some species use only environmental cues whilst others rely only on inherited changes, with many species falling somewhere in between these two extremes (Matsuura *et al.*, 2018). For example some ant species from the *Pogonomyrmex* genus have purely genetic caste determination (Mott *et al.*, 2015). On the other hand, many ant species undergo caste determination in response to only the environment, indicating their genomes must contain the code for all caste possibilities, with the phenotype potentially determined by epigenetic factors (Bonasio *et al.*, 2012).

Multiple epigenetic mechanisms have been associated with social insect plasticity. Histone modifications have been shown to be involved with plasticity, for example changes in histone acetylation alter the behaviour of major workers of the ant species *Camponotus floridanus*, making them more similar to the behaviour of minor workers (Simola *et al.*, 2016). Variation in microRNA expression levels has been identified in both honeybee (Ashby *et al.*, 2016) and bumblebee (Collins *et al.*, 2017) castes. However, the most active research in this area has been focused on DNA methylation (Glastad *et al.*, 2015).

DNA methylation is the addition of a methyl group to a cytosine nucleotide. In mammals, methylation primarily occurs in a CpG context (CpG referring to a cytosine base immediately followed by a guanine base), the percentage of CpG's methylated is usually over 70%, with methylation serving to repress gene expression when occurring in promoter regions (Feng *et al.*, 2010). However, in insects it is generally found in much lower quantities, ranging from zero methylation in most Diptera species studied, to >2% in Hymenoptera and up to 14% in some species of Blattodea (Provataris *et al.*, 2018). It is also enriched in gene bodies rather than throughout the genome, as in mammals (Fang

et al., 2012; Wang *et al.*, 2013), with a possible role in alternative splicing (Bonasio *et al.*, 2012).

DNA methylation has been associated with the switching of worker castes in honeybees (Herb *et al.*, 2012). A major finding was that silencing of the *Dnmt3* gene (involved in methylation establishment) in larvae produced queens rather than workers (Kucharski *et al.*, 2008). DNA methylation has also been linked with alternative splicing differences between castes in two ant species (Bonasio *et al.*, 2012) and is thought to be involved in caste determination in *Copidosoma koehleri*, a species of primitively social wasp (Shaham *et al.*, 2016). However, it is clear DNA methylation is not a conserved mechanism in Hymenoptera for caste differentiation. No association between caste and methylation has been found in a number of wasp and ant species (Patalano *et al.*, 2015; Standage *et al.*, 2016). Additionally, the statistical methods of previous next generation sequencing analyses on social insect methylation have been brought into question (Libbrecht *et al.*, 2016).

A greater variety of species are needed to begin to understand the role of DNA methylation in social insect caste determination. Here, we assess whole genome methylation differences between reproductive castes of the bumblebee, *Bombus terrestris*, with an aim to investigate the role of methylation in caste determination in this species. Bumblebees are primitively eusocial and are an important pollinator species, both economically and environmentally. They are generalist pollinators and are keystone species in some ecosystems (Woodard *et al.*, 2015). *B. terrestris* colonies are annual and are founded by a singly-mated queen in early spring, she will lay diploid eggs resulting in female workers and later switch to male haploid eggs, known as the switching point (Bloch, 1999). A competition phase then occurs between queens and workers, where some workers will become reproductive and produce their own haploid sons (Alaux *et al.*, 2006), this results in distinct reproductive worker castes within the colony. Multiple recent studies have highlighted *B. terrestris* as an ideal organism to assess methylation as a potential regulatory mechanism for reproductive caste determination (Amarasinghe *et al.*, 2014; Lonsdale *et al.*, 2017; Li *et al.*, 2018).

Methylation regulatory genes were identified in the bumblebee genome and have since

been shown to have varying expression levels between queens, workers and drones (Li *et al.*, 2018). Additionally, genes showing allele-specific methylation and gene expression have been identified and are enriched in reproductive related processes (Lonsdale *et al.*, 2017). Finally, experimental changes in methylation in *B. terrestris* workers has been shown to alter levels of reproductive behaviour (Amarasinghe *et al.*, 2014). Whilst these studies highlight differences in methylation between *B. terrestris* castes it is still unclear where those differences are within the genome and also whether methylation differences are related to changes in gene expression, potentially leading to caste differentiation.

In this study, I compared whole genome bisulfite sequencing data sets from reproductive and sterile worker castes of *B. terrestris*, allowing me to identify differences in methylation at base-pair resolution throughout the genome. I then linked these data with gene expression data for the same individuals to identify a potential relationship between gene expression and methylation regarding reproductive caste determination. Within this study I have also characterised the *B. terrestris* methylome in order to allow comparative analyses between castes. If methylation plays a role in caste determination I would expect to find differentially methylated genes between castes, with functions related to reproduction. I would also expect any differentially methylated genes between castes to be enriched for differentially expressed genes or genes which have different exon usage between castes. Additionally if there is a conserved role for methylation in caste determination in Hymenoptera I would expect to find orthologous genes differentially methylated between *B. terrestris* reproductive castes and *A. mellifera* reproductive castes.

2.3 Methods

2.3.1 Bee husbandry and tissue sampling

Eight *B. terrestris* colonies, from Agralan, UK, were reared in constant red light at 26°C and 60% humidity (Fig. 2.1a). They were fed 50% v/v apiary solution (Melirose-Roquette, France) and pollen (Percie du set, France) *ad libitum*. Callow workers, less

than 24 hours old (Fig. 2.1c), were taken from each colony and placed in small rearing boxes of five individuals (Fig. 2.1d).

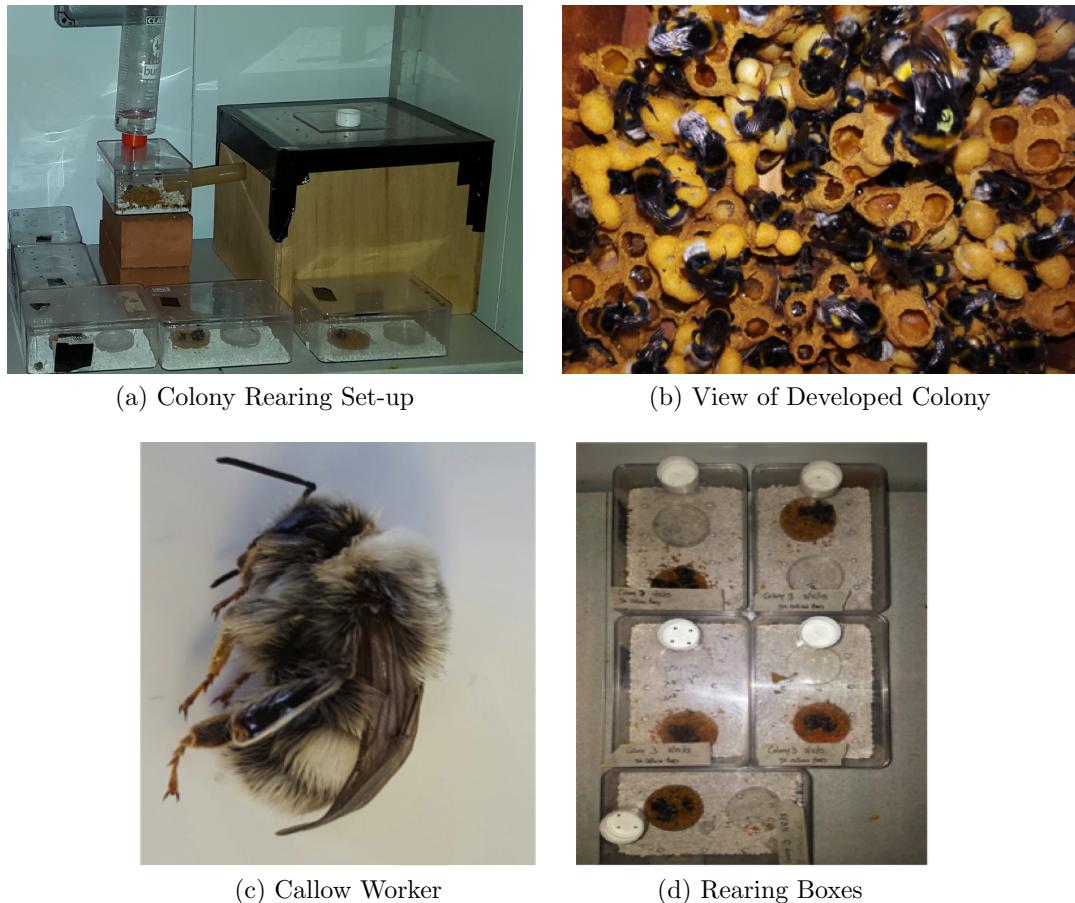

Figure 2.1: (a) Wooden colony box with attached foraging area, containing constant supply of sugar water and a dish of pollen grains. (b) Internal view of the wooden colony box, the queen can be seen at the top right with a yellow distinguishing mark, made by nail polish. (c) Sedated callow worker (individual <24 hours old, distinguished by the grey colouring and wings curled around the abdomen. (d) Rearing boxes containing five individuals, lined with cat litter and supplied with sugar water and pollen in petri dishes.

The worker bees were sacrificed at six days old. For each bee, the head was snap frozen in liquid nitrogen. Through dissection in 1% PBS solution, the reproductive status of each bee was determined and classed as either reproductive, sterile, or intermediate. Workers were classed as having developed ovaries, and therefore reproductive, if the largest oocyte was larger than the trophocyte follicle (Duchateau and Velthuis, 1988). This measurement is tightly correlated with reproductive status (Geva *et al.*, 2005;

Foster *et al.*, 2004). The ovaries of each worker were weighed, and the length of the largest oocyte was measured using ImageJ v.1.50e (Schneider *et al.*, 2012). Worker ‘reproductiveness’ was classified on a scale from 0-4 based on Duchateau and Velthuis (1988), 0 begin completely sterile (Fig. 2.2a) and 4 having fully developed ovaries (Fig. 2.2b).

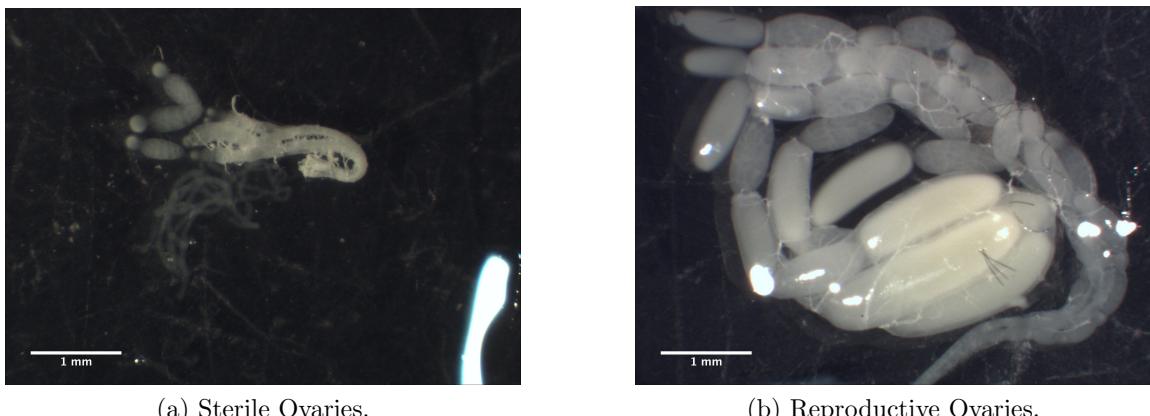

Figure 2.2: (a) single ovary without developed oocytes from a sterile worker, reproductive score = 0. (b) single ovary containing developed oocytes from a reproductive worker, reproductive score = 4.

2.3.2 RNA and DNA extraction and sequencing

Three reproductive individuals and three sterile individuals, sampled from the queenless rearing boxes, were selected for RNA and DNA extraction, see Figure 2.3 for an overview. Heads were cut in half (using a lateral incision central between the eyes). Each head half was randomly allocated for either DNA/RNA extraction to avoid left/right hemisphere bias. RNA was extracted using the Sigma-Aldrich GenElute Mammalian Total RNA Miniprep kit and DNA was extracted using the Qiagen DNeasy blood and Tissue kit, individually for each half head per sample, following manufacturers protocols. The extracted RNA was treated with DNase and the extracted DNA was treated with RNase. DNA was pooled per colony and reproductive status, i.e. the three reproductive samples from a single colony were pooled to create one representative reproductive sample for that colony (Fig. 2.3). RNA samples were processed individually. DNA and RNA quality and quantity was determined by Nanodrop and

Qubit® fluorometers. A total of 18 RNA samples (three individuals per reproductive status for each of the three colonies) were sent for 100bp paired-end sequencing and six pooled DNA samples (one sample per reproductive status per colony consisting of three individuals per pool) were sent for 100bp paired-end bisulfite sequencing on a HiSeq 2000 machine (Illumina, Inc.) by BGI Tech Solution Co., Ltd.(Hong Kong). Library preparation was carried out by BGI. A 1% lambda spike was included as an unmethylated control in each whole genome bisulfite sequencing (WGBS) library. Directional bisulfite libraries were prepared by fragmenting genomic DNA to 100-300bp by sonication, DNA-end repair was then carried out along with ligation of methylated sequencing adaptors. The ZYMO EZ DNA Methylation-Gold kit was used for bisulfite treatment with subsequent desalting, size selection, PCR amplification and final size selection before sequencing. RNA-seq libraries were prepared by using magnetic beads with an Oligo (dT) to enrich for mRNA, the mRNA was then fragmented and cDNA was synthesised using random hexamer priming, size selection and PCR amplification were then carried out prior to sequencing.

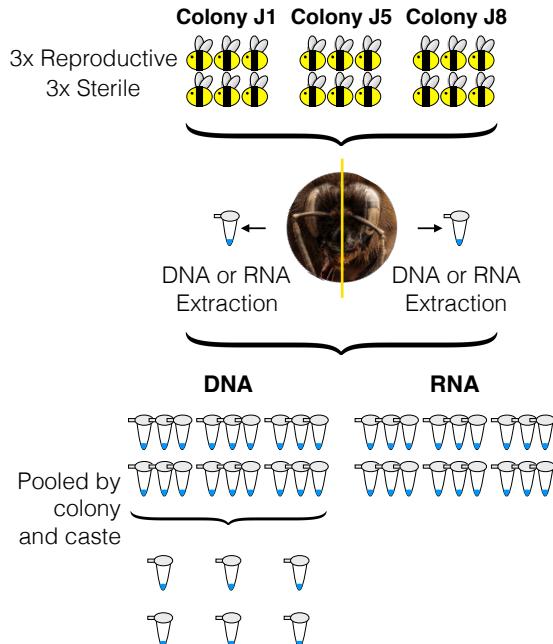

Figure 2.3: Overview of sample preparation for sequencing. Three *Bombus terrestris* reproductive workers and three sterile workers were selected from three colonies (J1, J5 and J8 represent colony names). Half of each head was randomly allocated for RNA/DNA extraction. All 18 RNA samples were sent for RNA-Seq (three of each caste from each colony). DNA samples were pooled by colony and caste creating a representative reproductive and sterile samples per colony.

2.3.3 Differential expression and alternative splicing

Low quality bases were removed from the RNA-Seq libraries using CutAdapt v1.1 (Martin, 2011). Reads were aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1 (Sadd *et al.*, 2015)) using STAR v2.5.2 (Dobin *et al.*, 2016) with standard parameters. Reads were counted per gene using HTseq v0.10.0 (Anders *et al.*, 2015). Differential expression analysis was then carried out after count normalisation via a negative binomial generalised linear model implemented by DEseq2 v1.20.0 (Love *et al.*, 2014) in R v.3.4.0 (<http://www.R-project.org>) with colony and reproductive status as independent variables. Genes were classed as differentially expressed when $q < 0.05$ after correction for multiple testing using the Benjamini-Hochberg method (Benjamini and Hochberg, 1995).

Differential exon expression was determined using the DEXseq v1.26.0 R package (An-

ders *et al.*, 2012), briefly this package calculated the ratio of expression of a given exon in a given gene relative to other exons in the same gene for each sample. The relative exon expression per colony was then calculated taking into account dispersion between colonies. A general linear model was then used to test for a difference in the relative proportion of expression of each exon between castes, accounting for sample differences and overall gene expression differences between castes, p-values were corrected for multiple testing using the Benjamini-Hochberg method (Benjamini and Hochberg, 1995) and exons were classed as differentially used between castes when $q < 0.1$. The benefit of this method over general alternative splicing analysis is that specific differentially used exons can be identified between castes allowing the relationship with exonic methylation to be investigated.

2.3.4 Differential methylation

WGBS libraries were aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1, (Sadd *et al.*, 2015)) using Bismark v.0.16.1 (Krueger and Andrews, 2011) and bowtie2 v.2.2.6 (Langmead and Salzberg, 2012) with standard parameters. Bismark was also used to extract methylation counts and carry out deduplication. Annotation of the methylation counts with genomic features (from the *B. terrestris* annotation file, Refseq accession no. GCF_000214255.1) was carried out using custom R scripts implementing the sqldf v.0.4.11 library (Grothendieck, 2017). Bisulfite conversion efficiency was calculated by aligning reads to the lambda reference genome (Refseq accession no. GCF_000840245.1) and calculating the single-site methylation level as in Schultz *et al.* (2012).

Prior to differential methylation analysis, coverage outliers (above the 99.9th percentile) were removed along with bases covered by less than 10 reads. The methylation status of each CpG was then determined using the ‘methylation status calling’ (MSC) procedure, as described in Cheng and Zhu (2014). Briefly, this involves applying a mixed binomial model to each CpG which includes estimation of both the false discovery rate and the non-false discovery rate in order to make a binary methylation call per site. CpG sites were then filtered to remove any site that did not return as methylated in at least

one sample. This functions to reduce the number of tests and hence decreases the required stringency of the later FDR correction applied during differential methylation testing. This is a vital step for species, such as bumblebees, with extremely low genome methylation where the majority of sites show zero methylation in all samples. A logistic regression model was then applied, via the R package methylKit v1.6.1 (Akalin *et al.*, 2012), to determine differentially methylated sites, taking into account colony as a covariate due to high inter-colony variation. A minimum difference of at least 10% methylation and a q-value of <0.05 were required for a single site to be classed as differentially methylated. Genes containing at least one differentially methylated CpG and a minimum weighted methylation difference of 10% across the entire gene were classed as differentially methylated between reproductive castes. Weighted methylation level is determined as the total number of methylated cytosines (C) within a region (i) divided by the total coverage of a region (Equation 2.1), as described in Schultz *et al.* (2012).

$$\sum_{i=1}^n C_i / \sum_{i=1}^n C_i + T_i \quad (2.1)$$

A permutation test was computed as part of the differential methylation analysis, as seen in previous research (Arsenault *et al.*, 2018; Libbrecht *et al.*, 2016). After removal of positions containing zero methylation for every sample and filtering by coverage, the sample labels for data at each CpG were randomly shuffled 10,000 times. A logistic regression was carried out for each random data set using methylKit.

2.3.5 GO enrichment

Gene ontology terms for *B. terrestris* were taken from a custom database from Bebane *et al.* (2019). GO enrichment analysis was carried out using a hypergeometric test with Benjamini-Hochberg (Benjamini and Hochberg, 1995) multiple-testing correction. GO terms were defined as enriched when $q < 0.05$. GO terms from differentially methylated genes were tested for enrichment against GO terms associated with all methylated

genes. Genes were classed as methylated when the weighted methylation score per gene was greater than zero (Schultz *et al.*, 2012). Additionally the GO terms associated with hypermethylated genes (i.e. genes with higher methylation levels in one condition compared to the other) in either sterile or reproductive workers were tested for enrichment against the GO terms associated with all differentially methylated genes between castes to determine if there are different functions for hypermethylated genes in either sterile or reproductive workers. GO terms for differentially expressed genes and genes containing different exon usage between castes were tested for enrichment against GO terms associated with all genes identified in the RNA-seq data. REVIGO (Supek *et al.*, 2011) was used to obtain the GO descriptions from the GO identification numbers.

2.3.6 Comparative analyses

The hypergeometric test was applied to gene lists from the various analyses to determine if any overlaps were statistically significant. Custom R scripts were used to investigate the relationship between gene expression and methylation. A reciprocal blast between the honeybee (Amel_4.5, Refseq accession no. GCA_000002195.1) and bumblebee genome (Bter_1.0, Refseq accession no. GCA_000214255.1) was carried out using blast+ v2.5.0 (Camacho *et al.*, 2009), where the fasta sequence for each gene of each species was blasted against a custom database containing the fasta sequence for every gene of the opposite species, allowing only one match per gene and a minimum e-value of 1×10^{-3} . The results were then filtered to ensure only matches that occurred in both directions and to only one gene were used. For example, multiple honeybee genes matched the same bumblebee gene, therefore all of these matches were discarded. This allowed us to construct a database of putative orthologous genes. A custom script was then used to check for overlap between the differentially methylated genes identified here and differentially methylated genes identified in Lyko *et al.* (2010) between honeybee reproductive castes.

All bioinformatic scripts used within this chapter can be found at: <https://zenodo.org/badge/latestdoi/162321404>.

2.4 Results

2.4.1 Collection of reproductive castes

From the eight reared colonies a total of 46 boxes of five callow workers were collected (totalling 230 individuals). The majority of females were classed as either reproductive (ovary score of 3-4) or sterile with only some individuals falling in the intermediate stage (ovary score of 1-2) (Fig. 2.4a). The mean weight of the ovaries along with the mean oocyte length for intermediate and reproductive workers can be found in Table 2.1. Reproductive workers had significantly heavier ovaries than both intermediate and sterile workers and intermediate workers had significantly heavier ovaries than sterile workers (Kruskal-Wallis test: chi-squared = 124.5, df = 2, p <0.000, Wilcoxon rank sum test: sterile and intermediate p <0.000, sterile and reproductive p <0.000 and intermediate and reproductive p <0.000)(Fig. 2.4b). Reproductive workers had significantly longer oocytes than intermediate workers (t-test: t = -10.367, df = 85.815, p <0.000)(Fig. 2.4c). Samples were selected from three colonies, as biological replicates (supplementary 1.0.0).

Table 2.1: Mean ovary weight and mean oocyte length with standard deviation for all samples from each of the three worker reproductive classifications.

Reproductive Status	Mean Ovary Weight (g)	Standard Deviation (g)	Mean Oocyte Length (mm)	Standard Deviation (mm)
Reproductive (score 3-4)	0.0164	+/- 0.01	1.633	+/- 0.39
Intermediate (score 1-2)	0.0075	+/- 0.003	0.981	+/- 0.24
Non-Reproductive (score 0)	0.0026	+/- 0.0019	N/A	N/A

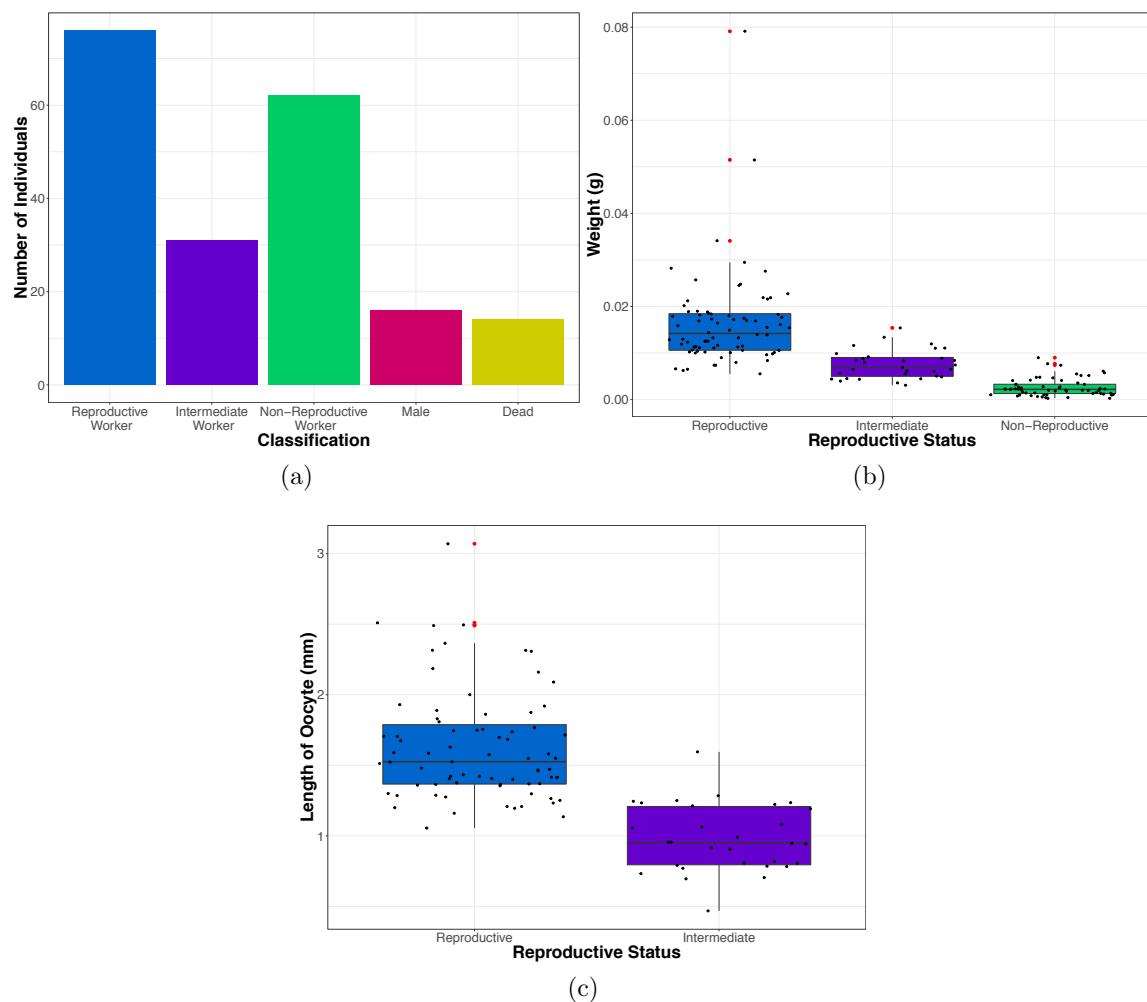

Figure 2.4: (a) Bar plot showing the total number of individual *Bombus terrestris* samples collected per reproductive classification, including any male samples taken by mistake and the number of individuals which died during rearing. (b) Boxplots of the weight of the ovaries collected from workers per each reproductive classification. Each boxplot shows the median along with the 25th and 75th percentile. The whiskers represent 1.5X the interquartile range. Outliers are represented as additional red points. Each offset black point represents an individual sample. Reproductive N = 76, intermediate N = 31 and non-reproductive N = 62. (c) Boxplot of the length of the largest oocyte of reproductive and intermediate workers.

2.4.2 DNA and RNA extraction

DNA extracted from half a head was pooled from three reproductive workers and three sterile workers per colony. This gave more than 1 μ g for each colony specific sample. Quality scores were all within acceptable ranges for sequencing (supplementary 1.0.1)

and DNA fragment sizes were generally above 10,000bp but with a smear of smaller fragments present (Fig. 2.5). RNA extracted from the second half of the head of each bee also gave acceptable quantity and quality scores for sequencing (supplementary 1.0.2).

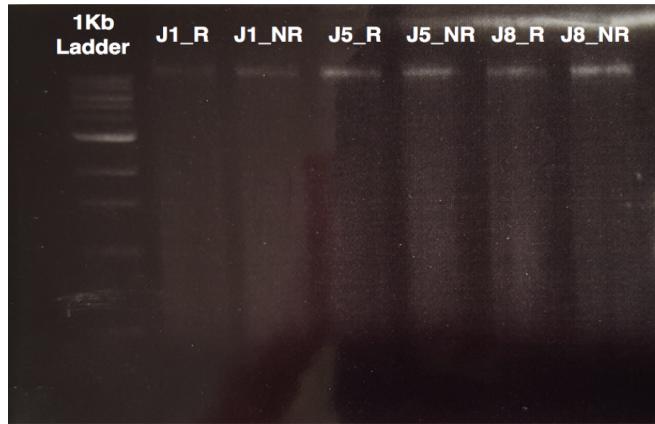

Figure 2.5: 1% agarose gel showing the DNA bands for all *Bombus terrestris* samples. There is a band above 10,000bp for all samples and they all show a smear of smaller fragments.

2.4.3 Genome-wide methylation differences between castes

Up to a maximum of 10bp were trimmed from the start of all reads due to base bias generated by the Illumina sequencing protocol (Krueger *et al.*, 2011). The mean mapping efficiency was $63.6\% \pm 1.4\%$ (mean \pm standard deviation) and the mean coverage was 17.7 ± 0.5 reads per base. The average number of uniquely mapped reads were $27,709,214 \pm 753,203$. The mean bisulfite conversion efficiency, calculated from the unmethylated lambda spike, was $99.55\% \pm 0.02\%$. After accounting for the conversion efficiency there were no methylated cytosines in a non-CpG context. The mean single site methylation level (Schultz *et al.*, 2012) in a CpG context was determined as $0.22\% \pm 0.07$, calculated from the number of methylated cytosines divided by the sum of methylated and unmethylated cytosines and accounting for bisulfite conversion efficiency.

A total of 3,412 genes were classed as methylated, i.e. they had a weighted methylation level greater than the conversion error rate of >0.05 in at least one sample. There

was no significant difference in the overall weighted methylation level of the methylated genes between reproductive and sterile workers (Mann-Whitney U test: $W = 5948300$, $p = 0.117$, Fig. 2.6a). GO terms enriched in methylated genes compared to all genes annotated in the genome ($q < 0.05$) include a large variety of biological processes (supplementary 1.0.3). The GO terms: *post-transcriptional regulation of gene expression* (GO:0010608), *histone modification* (GO:0016570) and *chromatin remodelling* (GO:0006338) are enriched as well as terms related to reproductive processes, e.g. *reproduction* (GO:0000003), *gamete generation* (GO:0007276), *oogenesis* (GO:0048477) and *oocyte differentiation* (GO:0009994).

There was no significant difference in the weighted methylation level of any genomic feature (e.g. exon, intron, gene) between reproductive and sterile workers (Two-way ANOVA, interaction between genomic feature and reproductive status; $F_{1,6} = 0.637$, $p = 0.701$, Fig. 2.6b). I also tested for differences in methylation levels of putative promotors but as promotor regions are currently unannotated for the current bumblebee genomic annotation I feel these results are not reliable (Fig. 2.6b). Irrespective of worker reproductive status we found methylation differences between genomic features (Kruskal-Wallis; chi-squared = 729.35, $df = 7$, $p < 0.000$). With methylation being significantly enriched in coding regions compared to introns and ncRNAs (supplementary 1.0.6).

I also found no difference in the weighted methylation level across the genome per linkage group between reproductive and sterile workers (Two-way ANOVA, interaction between linkage group and reproductive status; $F_{1,17} = 0.034$, $p = 1$, Fig. 2.7). Weighted methylation did vary significantly between linkage groups within the genome irrespective of reproductive status (Kruskal-Wallis chi-squared = 131.59, $df = 17$, $p < 0.000$, supplementary 1.0.6). However, due to the number of unplaced scaffolds these results should be interpreted with care.

Finally, using CpG methylation levels, samples cluster by colony rather than by reproductive caste (Fig. 2.6c and 2.6d). This indicates high inter-colony variation in methylation.

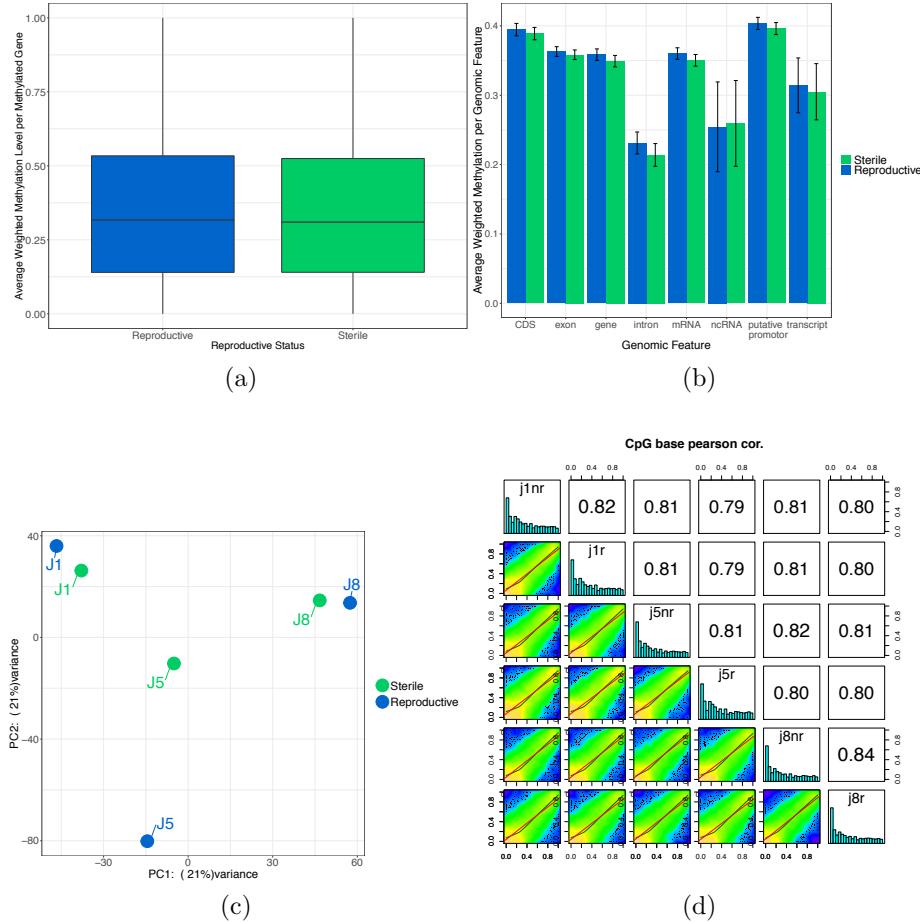

Figure 2.6: (a) Box plot of the mean weighted methylation level of methylated genes ($N = 3412$) across *Bombus terrestris* colonies for each caste. Each boxplot shows the median along with the 25th and 75th percentile. The whiskers represent 1.5X the interquartile range. Outliers are represented as additional red points. (b) The mean weighted methylation level across colonies for each genomic feature for both reproductive and sterile workers. Error bars are 95% confidence intervals of the mean. This graph includes a putative promotor region, this was defined as 5000bp upstream of each gene annotation. As the current annotation file for *B. terrestris* does not include promotor regions. This result should be viewed with care as some of the ‘putative promotor’ regions also contain other annotated genomic features such as other genes and coding regions. (c) PCA plot generated by methylKit showing samples cluster by colony using per site CpG methylation. Total CpGs = 28,735,331. (d) Methylation correlation matrix of all samples in a CpG context. The numbers represent the pairwise correlation coefficients. The corresponding scatter plots are fitted with a linear regression (red line) and a polynomial regression, fit using the LOESS method (green line). The internal bar plots show the percentage of methylation per base.

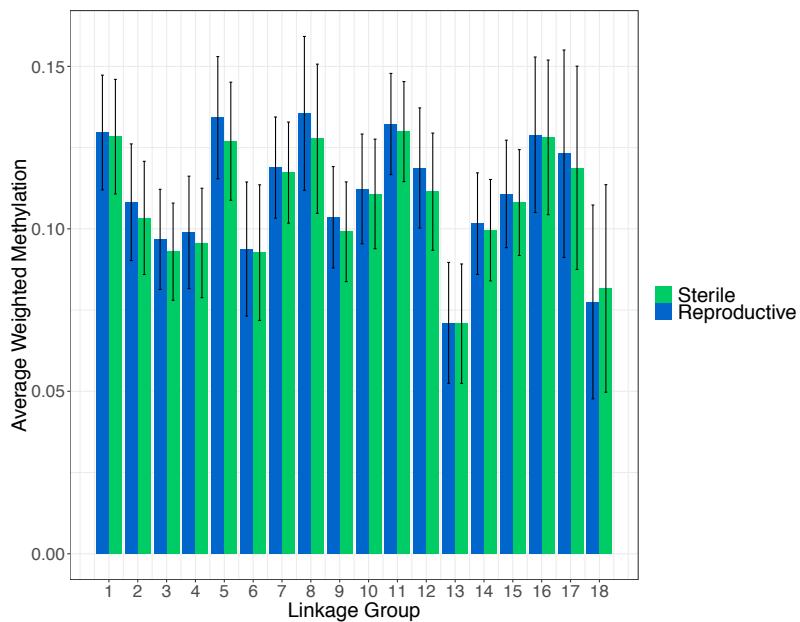

Figure 2.7: The mean weighted methylation level across *Bombus terrestris* colonies for each linkage group defined in the *B. terrestris* genome Bter_1.0 (NCBI Accession: GCA_000214255.1). Error bars are 95% confidence intervals of the mean. This figure should also be viewed with caution as currently there are >5,000 unplaced scaffolds for this genome build which are not included in the figure.

2.4.4 Gene level methylation differences between castes

A total of 4,681,131 CpG sites had a coverage >10 in all six sample data sets, of those 16,194 returned as methylated in at least one sample after running the MSC procedure. A total of 624 of these CpGs were identified as differentially methylated between reproductive castes, 613 of these were located in a total of 478 genes (supplementary 1.0.4). 11 differentially methylated CpGs were located outside of genes, nine of those were within 5000bp upstream or downstream of a gene with no apparent trend in the expression of near-by genes (supplementary 1.0.5). After stringent filtering of these genes to also require each gene to show a minimum weighted methylation difference of 10% we found 111 differentially methylated genes between reproductive and sterile workers (supplementary 1.0.7, Fig. 2.8).

Figure 2.8: Scatter plot of the average weighted methylation level (across *Bombus terrestris* colonies) for reproductive workers against sterile workers. Each dot represents a gene ($N = 3412$) and each red dot represents a differentially methylated gene ($q < 0.05$ and a minimum gene weighted methylation difference of 10%).

Of the 111 differentially methylated genes, there was no preference for genes to be hypermethylated in either reproductive or sterile workers (Chi-squared goodness of fit, chi-squared = 2.027, df = 1, p = 0.154), with 63 genes hypermethylated in reproductive workers and 48 genes hypermethylated in sterile workers.

GO terms enriched in differentially methylated genes compared to all methylated genes ($q < 0.05$) contained a variety of biological processes (supplementary 1.0.8), amongst these were terms involved with reproduction, including: *meiotic cell cycle* (GO:0051321), *maintenance of oocyte nucleus location involved in oocyte dorsal/ventral axis specification* (GO:0042070), *negative regulation of transcription involved in meiotic cell cycle* (GO:0051038), *female meiosis chromosome segregation* (GO:0016321) and *female germline ring canal stabilisation* (GO:0008335). One of the genes associated with the above GO terms is *eggless* (LOC100647514: *histone-lysine N-methyltransferase eggless*) which shows hypermethylation in sterile workers. This gene contains a Methyl-CpG binding domain which has been associated with histone H3, lysine 9-specific methyltransferase which contributes to repression of transcription (Wakefield *et al.*, 1999).

There were no specific GO terms enriched for either the hypermethylated genes in sterile workers or the hypermethylated genes in reproductive workers compared to all differentially methylated genes as a background.

A valid permutation test was not possible due to the structure within the data caused by colony (Fig. 2.9a). More sites were found to be differentially methylated using the random data as variation between colonies is higher than variation caused by reproductive status. Using this method 'colony' can no longer be taken into account as a consistent covariate and the effect therefore inflates the number of obtained differentially methylated sites (Fig. 2.9b).

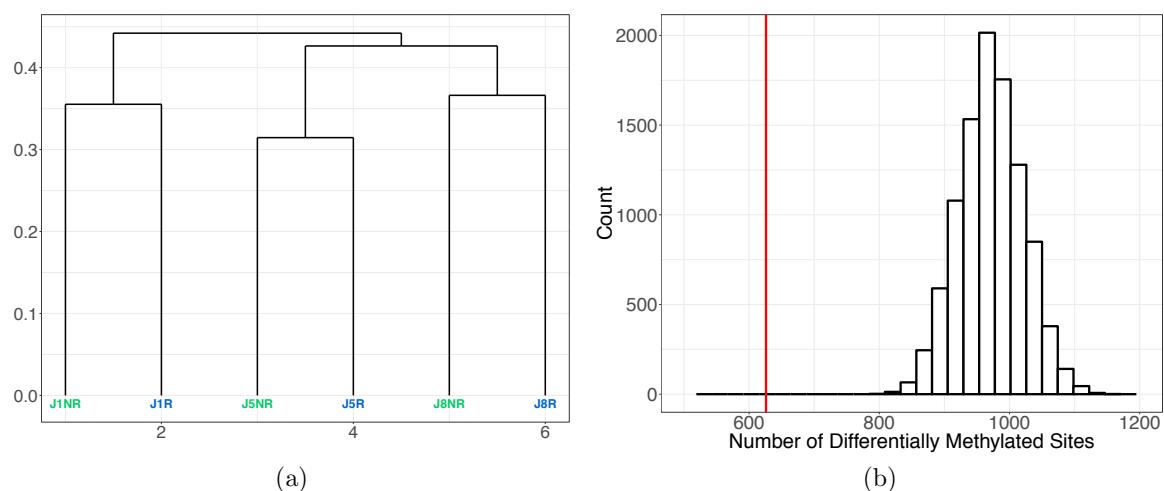

Figure 2.9: (a) Hierarchical cluster based on CpG ($N = 28,735,331$) methylation correlation distances for all *Bombus terrestris* samples, calculated using the 'ward' method. (b) Histogram of the number of differentially methylated sites obtained from 10,000 permutations. The red line indicates the number of sites observed from the un-shuffled data.

Whilst permutation tests are useful for some data sets, when structure is present in the data they become unreliable, as discussed in Winkler *et al.* (2015). A higher number of replicates would allow label shuffling within confounding factors, maintaining the structure of the data, thus allowing a permutation test.

2.4.5 Expression differences between worker reproductive castes

All reads had 13bp trimmed from the start due to base bias generated by the Illumina protocol (Krueger *et al.*, 2011). The mean percentage of uniquely mapped reads was $89.4\% \pm 0.8\%$ (mean \pm standard deviation). This equated to a mean of $10,115,366 \pm 1,849,600$ uniquely mapped reads. After running a differential expression analysis with DESeq2, the decision was made to remove one sample from all downstream analysis due to possible mislabelling of reproductive status.

Sample J8_24 was classed as reproductive but clustered with the sterile samples in both a principle component analysis (PCA) and a poisson distance matrix, taking into account expression levels of all genes (Fig. 2.10a and 2.10b). It also clustered with sterile samples in a hierarchical cluster using euclidean distances based on the top 100 differentially expressed genes (Fig. 2.10c). Including this sample led to a decrease in the number of differentially expressed genes identified (110 with sample, 334 without sample). After removal of this sample all other samples clustered by reproductive status (Fig. 2.11a, 2.11b and 2.11c).

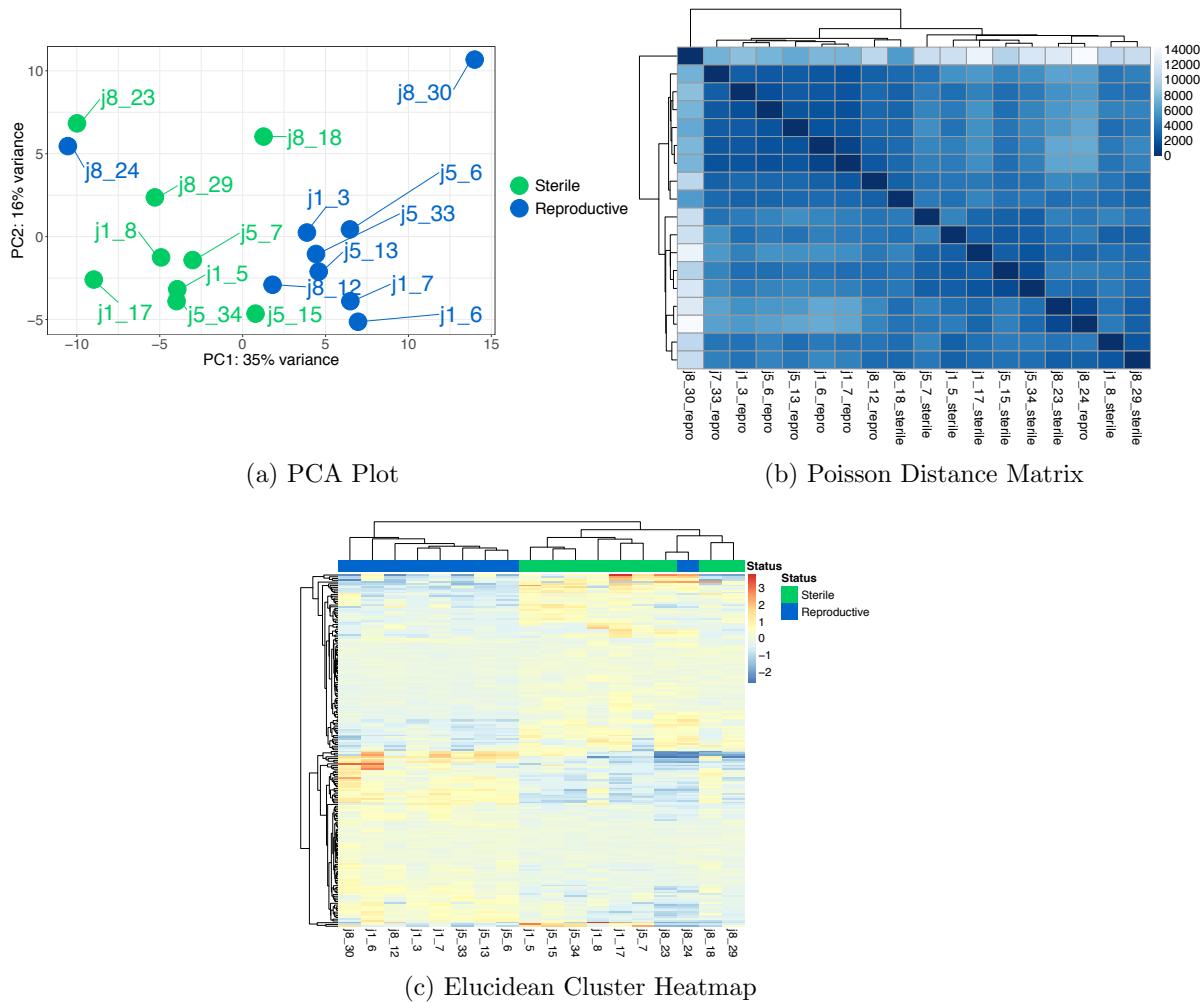

Figure 2.10: Graphs generated from differential expression analysis using DESeq2 for all *Bombus terrestris* samples. (a) PCA plot showing the different reproductive status' grouped together, based on the expression of all genes ($N = 11,732$). (b) Poisson measurement of dissimilarity between counts of all genes for each sample compared to every other sample. The lighter colours represent higher dissimilarity with other samples. The dendograms are mirrored and show hierarchical clustering of all samples. (c) Heatmap showing the top 100 differentially expressed genes in reproductive and sterile workers. Red colour indicates over-expression and blue colour indicates under-expression. The top dendogram shows hierarchical clustering by sample based on the counts of the genes shown. The left-hand dendrogram shows count similarity between the top 50 over expressed genes in reproductive workers and the top 50 over expressed genes in sterile workers.

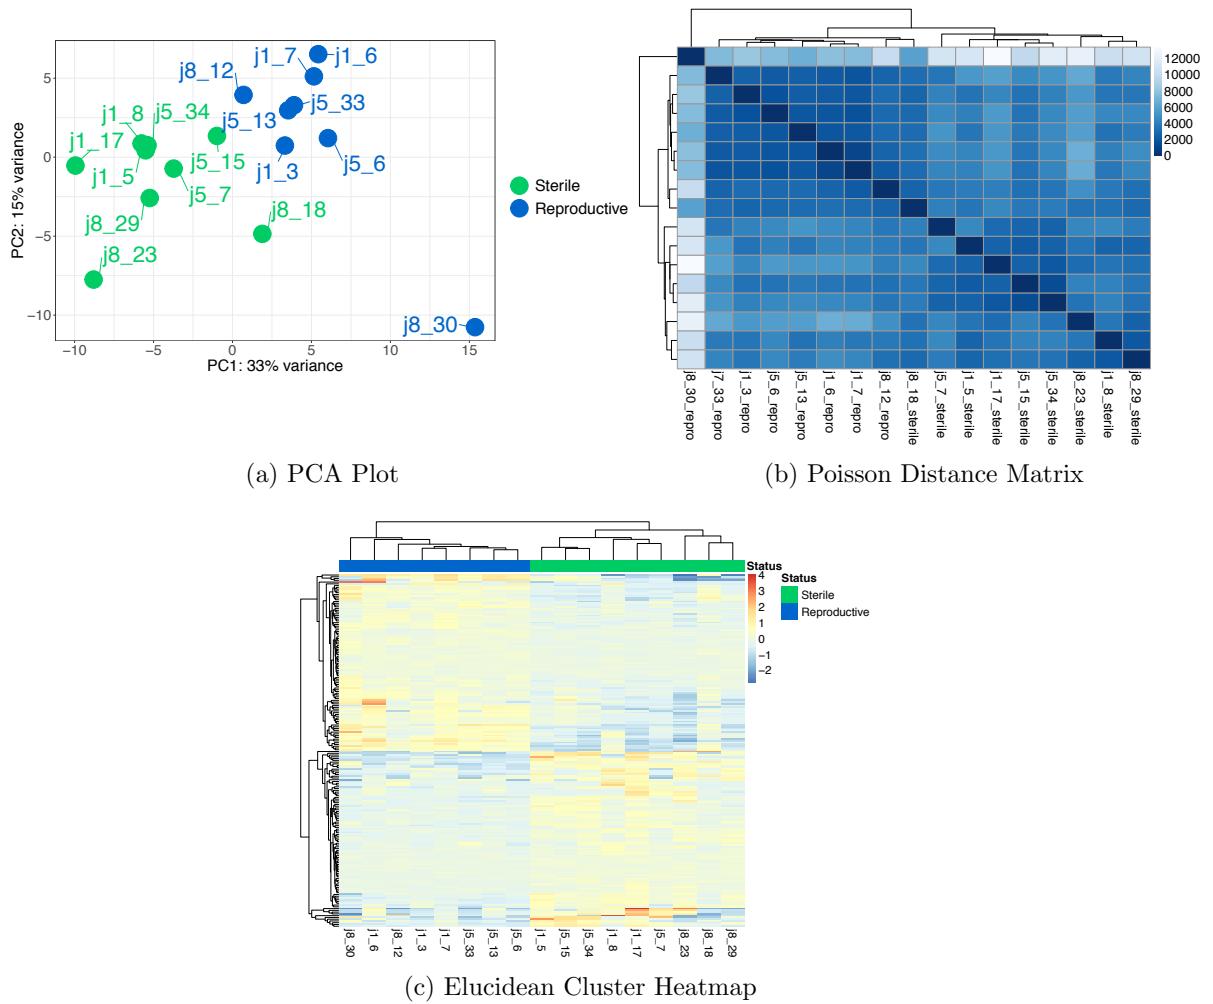

Figure 2.11: Graphs generated from differential expression analysis using DESeq2 for all *Bombus terrestris* samples, excluding J8_24. (a) PCA plot showing the different reproductive status' grouped together, based on the expression of all genes ($N = 11,732$). (b) Poisson measurement of dissimilarity between counts of all genes for each sample compared to every other sample. The lighter colours represent higher dissimilarity with other samples. The dendograms are mirrored and show hierarchical clustering of all samples. (c) Heatmap showing the top 100 differentially expressed genes in reproductive and sterile workers. Red colour indicates over-expression and blue colour indicates under-expression. The top dendogram shows hierarchical clustering by sample based on the counts of the genes shown. The left-hand dendrogram shows count similarity between the top 50 over expressed genes in reproductive workers and the top 50 over expressed genes in sterile workers.

A total of 334 genes were identified as differentially expressed ($q < 0.05$). There was no difference in the number of up-regulated genes in either reproductive or sterile workers (Chi-squared goodness of fit: chi-squared = 0.2994, df = 1, p-value = 0.584), with

172 genes up-regulated in reproductive workers and 162 genes up-regulated in sterile workers.

One of the most up-regulated genes in reproductive workers was vitellogenin (gene ID: LOC100650436, log₂ fold-change of 2.92, q = <0.000). Previous work has found up-regulation of this gene in reproductive *B. terrestris* workers is linked to aggressive behaviour rather than directly to ovary development (Amsalem *et al.*, 2014; Lockett *et al.*, 2016). Additionally two genes coding for serine-protease inhibitors were found to be up-regulated in reproductive workers, these proteins have been linked to reproduction in other insect species (Bao *et al.*, 2014).

Enriched GO terms associated with the differentially expressed genes compared to the background of all genes in the RNA-seq data (q <0.05) contained a variety of biological processes (supplementary 1.1.0), including *embryonic process involved in female pregnancy* (GO:0060136) and *positive regulation of oviposition* (GO:1901046). Additionally there were no specific GO terms enriched in up-regulated genes of reproductive workers compared to all differentially expressed genes as the background. However, there were two GO terms enriched for up-regulated genes in sterile workers compared to differentially expressed genes as the background, these were: *cellular lipid metabolic process* (GO:0044255) and *isoprenoid biosynthetic process* (GO:0008299).

A total of 59 genes were identified as having differential exon usage, containing 83 differentially expressed exons between reproductive castes (q <0.1, supplementary 1.1.1, Fig. 2.12). There is no difference in the number of up-regulated exons in reproductive workers compared to sterile workers (Chi-squared goodness of fit: chi-squared = 3.4819, df = 1, p-value = 0.06), with reproductive workers having 33 up-regulated exons and sterile workers having 50 up-regulated exons. The enriched GO terms associated with genes containing differentially used exons compared to the background of all genes in the RNA-seq data (q <0.05) contained a variety of biological processes (supplementary 1.1.2.). However, there were no GO terms with a clear connection to reproductive processes.

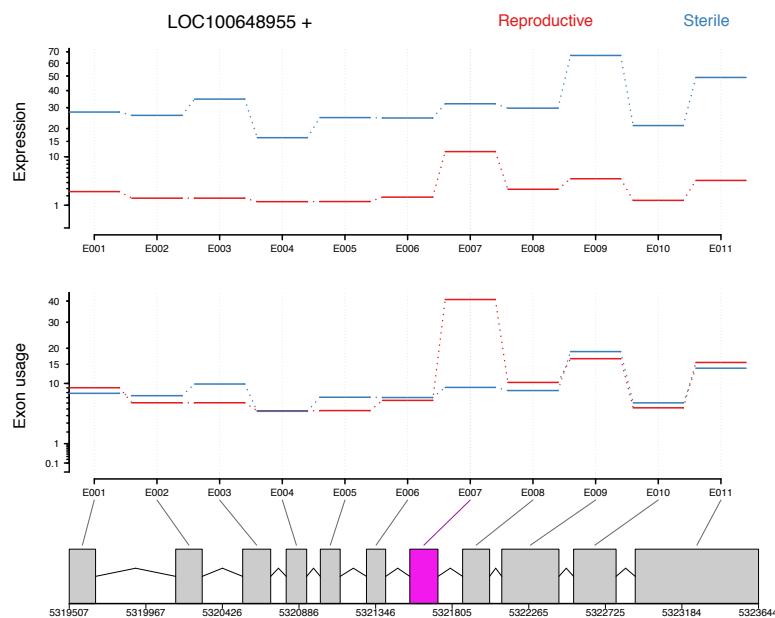

Figure 2.12: An example of a gene which shows differential exon expression in one exon between *Bombus terrestris* reproductive castes. The top section of the plot shows the general expression differences between castes, the second section shows the normalised counts per exon (given expression differences) and the third section highlights the differentially expressed exon in pink. Gene shown: *probable peroxisomal acyl-coenzyme A oxidase 1* (ID: LOC100648955).

Relationship of methylation and gene expression

On an individual gene basis, methylation and reproductive caste have no effect on expression level (Fig. 2.13a and 2.13b, linear mixed effects model with colony as a random factor; methylation: $df = 49172$, $t = -1.295$, $p = 0.195$, reproductive status: $df = 49172$, $t = -0.638$, $p = 0.524$, interaction between methylation and reproductive status: $df = 49172$, $t = 0.112$, $p = 0.911$).

However, gene groups with varying methylation levels show different levels of expression (Kruskal-Wallis; chi-squared = 131.59, $df = 17$, $p < 0.000$, Fig. 2.13c). Specifically genes with no methylation show higher expression than genes classed as lowly methylated but lower expression than genes classed as medium/high in terms of methylation (Dunn's test with Benjamini-Hochberg multiple-testing correction; no methylation vs low methylation: $Z = -13.14$, $p < 0.000$, no methylation vs medium methylation: $Z = 4.5$, $p < 0.000$, no methylation vs high methylation: $Z = 7.32$, $p < 0.000$, Fig. 2.13c).

Reproductive caste still has no effect on gene expression in relation to methylation status when genes are grouped (Two-way ANOVA, interaction between reproductive status and methylation level; $F_{1,3} = 0.017$, $p = 0.99$).

A linear mixed effects model was then applied to assess the relationship between gene expression, methylation and reproductive status for only methylated genes using colony as a random factor. There is a positive relationship between gene expression and methylation in methylated genes with reproductive status having no effect (Fig. 2.13d, methylation: $df = 17390$, $t = 6.154$, $p < 0.000$, reproductive status: $df = 17390$, $t = -0.328$, $p = 0.743$, interaction between methylation and reproductive status: $df = 17390$, $t = -0.200$, $p = 0.842$).

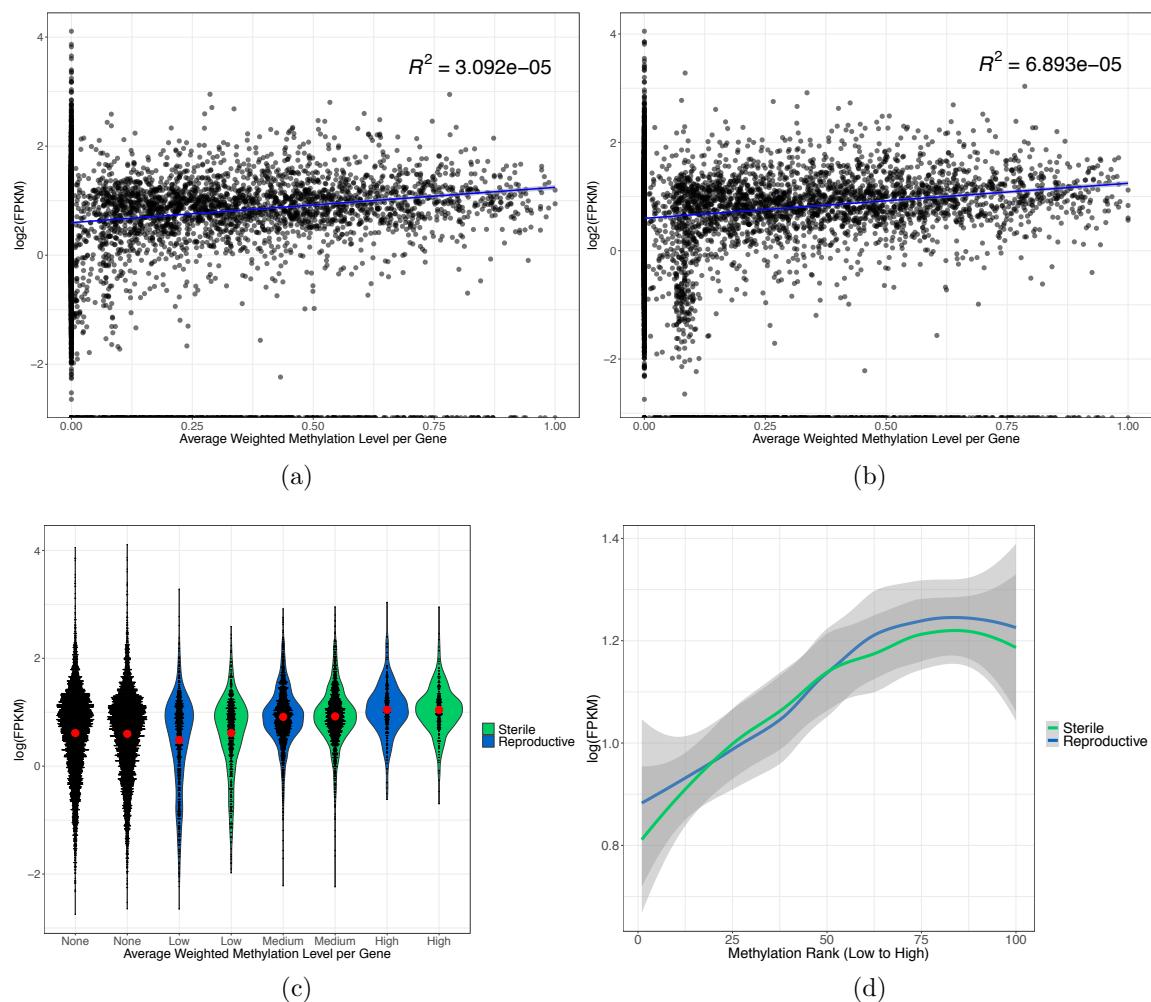

Figure 2.13: (a) and (b) the colony average weighted methylation level for every gene plotted against the log(FPKM) of that gene ($N = 8,709$) for *Bombus terrestris* sterile workers and reproductive workers respectively. Each black dot represents a single gene. The blue line is a fitted linear regression with the grey shaded area representing 95% confidence intervals. (c) Violin plots showing the distribution of the data via a mirrored density plot, meaning the widest part of the plots represent the most genes. Weighted methylation level per gene per caste, averaged across colonies, was binned into four categories, no methylation (reproductive $N = 5,373$ and sterile $N = 5,474$), low ($>0 - 0.2$, reproductive $N = 1,075$ and sterile $N = 981$), medium ($0.2 - 0.7$, reproductive $N = 1,871$ and sterile $N = 1,883$) and high ($0.7 - 1$, reproductive $N = 390$ and sterile $N = 371$), as in Liu *et al.* (2019). The red dot indicates the mean with 95% confidence intervals. Each black dot represents a single gene. (d) Binned methylated genes ($N = 3412$, 100 being the most highly methylated) based on the mean weighted methylation level across colonies per reproductive caste, plotted against the log(FPKM) expression level per gene. Data were smoothed using the LOESS method, grey areas are 95% confidence intervals.

2.4.6 Relationship of methylation and differential gene expression

Weighted methylation differences between differentially expressed genes and non-differentially expressed genes were assessed along with weighted methylation differences between genes containing differentially expressed exons and genes without differentially expressed exons (Fig. 2.14a and Fig. 2.14b). Differentially expressed genes and genes containing differentially expressed exons between castes show lower methylation than non-differentially expressed genes or genes containing no differentially expressed exons, with reproductive status and the interaction of reproductive status with gene expression type having no effect (Table 2.2, Fig. 2.14a and 2.14b). When weighted methylation is assessed per exon, differentially expressed exons have lower weighted methylation than non-differentially expressed exons (Fig. 2.14c), with reproductive status and the interaction of reproductive status and exon expression having no effect (Table 2.2).

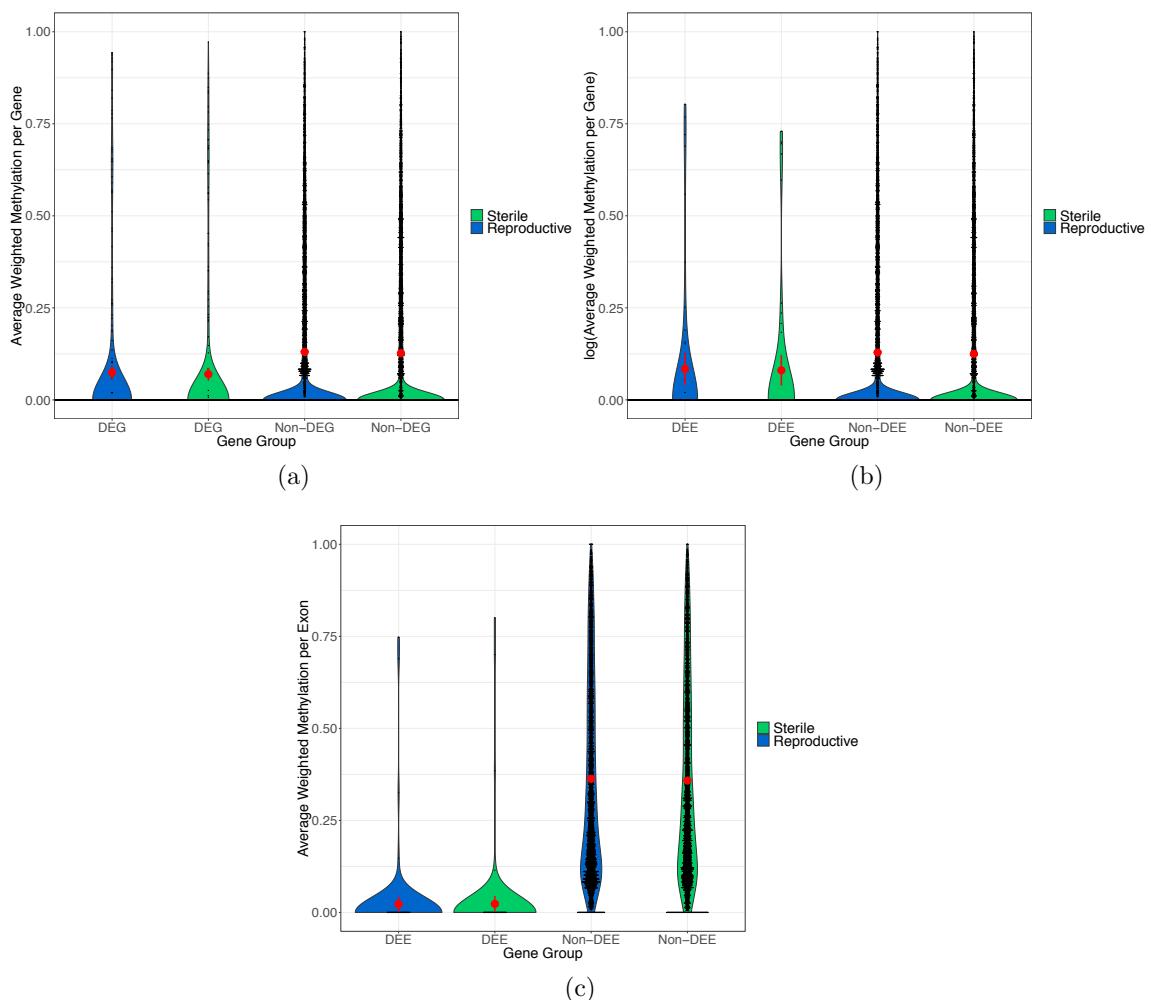

Figure 2.14: (a) Violin plots showing the distribution of the data via a mirrored density plot, meaning the widest part of the plots represent the most genes. The red dots represent the mean of each gene set along with error bars representing 95% confidence intervals of the mean. Each black dot is an individual gene. The mean weighted methylation per gene across *Bombus terrestris* colonies per caste is plotted for either differentially expressed genes (DEG, N = 334) or non-differentially expressed genes (non-DEG, N = 7,911). (b) Violin plots of the mean weighted methylation per gene across colonies per caste is plotted for either genes containing differentially expressed exons (DEE, N = 59) or genes with no differentially expressed exons (non-DEE, N = 8,147). (c) Violin plots of the mean weighted methylation per exon across colonies per caste for differentially expressed exons (DEE, N = 59) and non-differentially expressed exons (non-DEE, N = 3,011). The red dots represent the mean of each gene set along with error bars representing 95% confidence intervals of the mean. Each black dot is an individual exon.

Table 2.2: Summary statistics of the linear models used to check for differences in weighted methylation level between gene sets, taking into account reproductive status. The interaction vs main effects models were tested using the *anova* function in R to assess the interaction effect between gene set and reproductive status. * indicates a significant p-value <0.05.

	Res.Df	RSS	Df	Sum of Sq	F	P

Of the 334 differentially expressed genes, 50 also showed some level of weighted methylation difference between reproductive and sterile workers (weighted methylation difference >0) (Fig. 2.15a). However, there is no relationship between the level of differential methylation and the level of differential expression for these 50 genes (linear model: $F_{1, 58} = 0.2717$, $p = 0.604$).

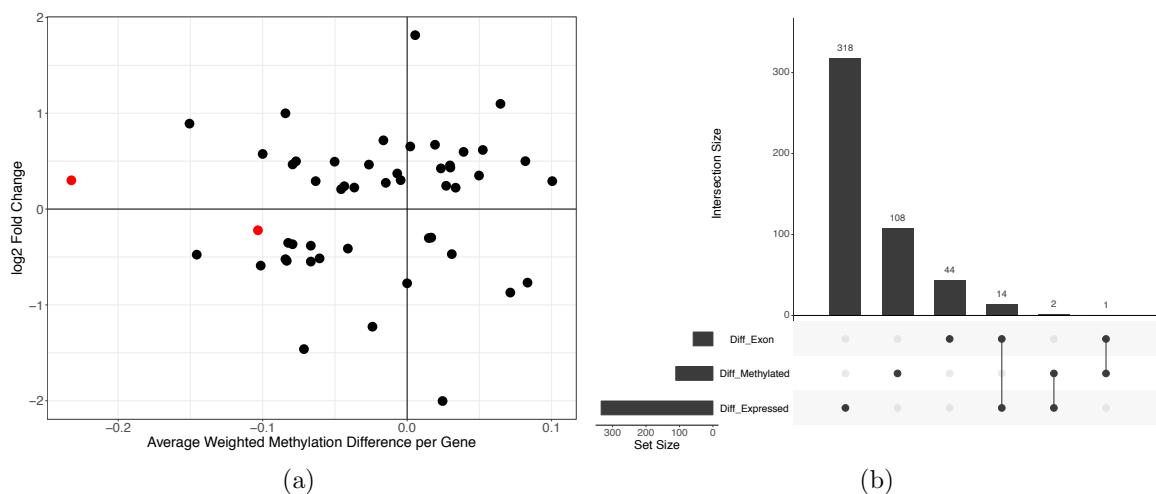

Figure 2.15: (a) Scatter plot of the difference in the mean weighted methylation level across *Bombus terrestris* colonies between castes plotted against the log₂ fold change in expression of differentially expressed genes between castes. Each dot represents a gene, only genes which have a methylation difference >0 are shown (N = 51). The red dots indicate the gene is also differentially methylated. (b) UpSet plot showing the number of common genes between analyses. The set size indicates the number of genes in each category: differentially expressed, differentially methylated or genes containing a differentially expressed exon. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list.

Gene lists were checked for potential overlap from all analyses. There was no significant overlap between differentially methylated genes and differentially expressed genes (two genes, hypergeometric test; p = 0.658, Fig. 2.15b). There was also no significant overlap between differentially methylated genes and genes containing differentially expressed exons (one gene, hypergeometric test; p = 0.12, Fig. 2.15b).

There was a significant overlap of genes found to be differentially expressed with those containing differentially expressed exons, 14 total (hypergeometric test; p < 0.000, Fig. 2.15b). All lists of overlapping genes can be found in supplementary 1.1.3.

Honeybee orthologous differentially methylated genes

Custom honeybee and bumblebee putative-ortholog databases were created from 15,314 and 10,339 annotated genes respectively (Amel_4.5 GCA_000002195.1, Bter_1.0

GCA_000214255.1). 9,244 honeybee genes matched at least one bumblebee gene and 7,985 bumblebee genes matched at least one honeybee gene with an e-value of $<1 \times 10^{-3}$. A total of 7,345 genes made the same match in both blast searches. Of these genes 392 matched more than one gene in one or both blasts and were therefore removed. This left a final putative ortholog list of 6,953 genes. 99 of the 111 differentially methylated genes identified here were present in the final putative ortholog list. However, none of them matched the 549 genes identified as differentially methylated between honeybee reproductive castes by Lyko *et al.* (2010) (Fig. 2.16).

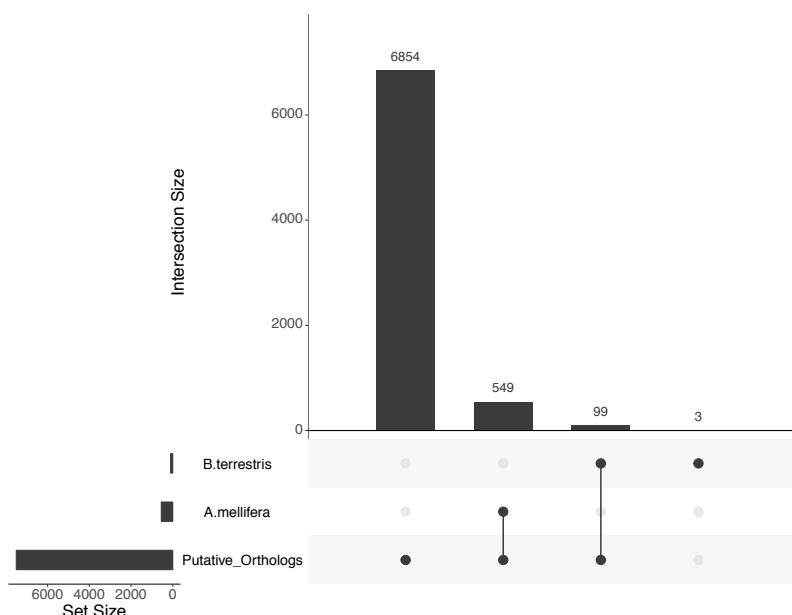

Figure 2.16: UpSet plot showing the number of putative orthologs between *A. mellifera* and *B. terrestris* along with the number of differentially methylated genes identified in Lyko *et al.* (2010) and in this study which are present in the putative ortholog database. The set size indicates the number of genes in each category. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list.

2.5 Discussion

I have used whole genome bisulfite sequencing and gene expression libraries from the same individual *B. terrestris* workers to investigate the role of methylation in caste determination. I found both reproductive and sterile workers show similar methylation

patterns to other holometabolous insects. Methylation also has a similar relationship with gene expression compared to most other holometabolous insects currently studied, with more highly methylated genes showing higher levels of expression and lower levels of methylation being associated with differentially expressed genes. I found no methylation differences on a genomic scale between castes. However, 111 genes were differentially methylated. These were involved in a variety of functions including reproductive related processes. I found no relationship between genes that are differentially expressed, or contain differential exon usage between castes with those that show differential methylation between castes. Finally I also found no common putative orthologous genes differentially methylated between *B. terrestris* and *A. mellifera* reproductive castes.

This is the first data set to accurately quantify methylation at base-pair resolution for *B. terrestris* castes. It confirms low methylation levels throughout the genome as predicted by Sadd *et al.* (2015). These low levels along with enrichment for CpG methylation in coding regions are also seen in many social insect species, including *A. mellifera* (Lyko *et al.*, 2010) and multiple ant species (Bonasio *et al.*, 2012; Libbrecht *et al.*, 2016). These trends are also seen more generally in holometabolous insects (Provataris *et al.*, 2018). However, they are not completely conserved among all holometabolous insects, for example the primitively social wasp species *Polistes dominula* shows 6% CpG methylation (Weiner *et al.*, 2013), and the highly social termite, *Zootermopsis nevadensis*, has exceptionally high methylation levels compared to the majority of insects (Bewick *et al.*, 2016), with 12% CpG methylation, and methylation being just as common in introns as exons (Glastad *et al.*, 2016).

Higher levels of CpG methylation are associated with higher levels of gene expression in both *B. terrestris* reproductive castes. This is also the case in some other social insects, with Figures 2.13a and 2.13d showing almost identical trends to those found in Bonasio *et al.* (2012), Patalano *et al.* (2015) and Libbrecht *et al.* (2016). Additionally other social insect species, show higher methylation in non-differentially expressed genes as we found here, examples include: *Dinoponera quadriceps* (Patalano *et al.*, 2015), *Polistes canadensis* (Patalano *et al.*, 2015), *Zootermopsis nevadensis* (Glastad *et al.*, 2016) and *Cerapachys biroi* (Libbrecht *et al.*, 2016). Higher levels of methylation in more highly

expressed genes and in non-differentially expressed genes is thought to indicate a role for methylation in housekeeping genes in some holometabolous insects (Foret *et al.*, 2009; Lyko *et al.*, 2010; Bonasio *et al.*, 2012; Wang *et al.*, 2013; Provataris *et al.*, 2018). High levels of gene body methylation is also found in highly expressed genes in plants, whilst currently the function is unknown, Zilberman (2017) hypothesises it functions to stabilise expression by reducing histone variants and Bewick and Schmitz (2017) hypothesise it is a byproduct of transposable element silencing.

As well as a similar methylation profile to other social insects, I also predicted that if methylation plays a role in reproductive caste determination we would find differentially methylated genes between castes with reproductive related functions. I found 111 differentially methylated genes which include enriched GO terms for various reproductive related processes, this suggests methylation has some association with the switch between sterility and reproduction in *B. terrestris*. This supports previous work which exposed *B. terrestris* to a chemical which decreases general methylation levels and found workers were more likely to become reproductive (Amarasinghe *et al.*, 2014). However, we did not find a difference in the genome-wide methylation levels of sterile and reproductive workers. It is also worth noting a worker classed as reproductive appeared to show a sterile transcriptional profile and this was included in the pool for the reproductive sample for colony J8. This will have ‘diluted’ the strength of the methylation profile for this particular sample. It is therefore likely our data contains false negatives, meaning there may be differentially methylated genes between reproductive castes which do not appear in our data set.

Whilst I found differentially methylated genes between castes I found no evidence for a relationship between methylation and gene expression in relation to reproductive and sterile workers. Only a small non-significant number of genes are both differentially methylated and differentially expressed between castes and there is no relationship between the degree of differential methylation and differential expression on a gene level. Previous research using the milkweed bug (*Oncopeltus fasciatus*) found knocking down *Dnmt1*, the gene responsible for DNA methylation maintenance, in ovary tissue with RNAi had no effect on gene expression. However, these individuals could no longer reproduce (Bewick *et al.*, 2019). This suggests methylation may play an alternative

role, rather than direct regulation of gene expression, in reproduction of some insects. Bewick *et al.* (2019) suggest this role may be the regulation of genome stability and/or the regulation of vital cellular processes. The variety of GO terms involved in biological processes we obtained for the differentially methylated genes between castes supports this idea.

Additionally, I observed high inter-colony variation in methylation. However, I did not have sufficient replicates to test for exact differences between colonies. High inter-colony variation could suggest methylation may also play a role in the adaptive abilities of *B. terrestris*. Stable environmentally induced ‘epialleles’ have been proposed to act as an additional layer of information for which selection can act upon (Flores *et al.*, 2013). However, we currently do not know if *B. terrestris* methylation shows transgenerational inheritance or whether a large proportion is wiped during development, as in mammals (Messerschmidt *et al.*, 2014).

It has also been suggested methylation may regulate alternative splicing, rather than expression in some insects (Glastad *et al.*, 2011). I found no evidence here for the role of exon methylation in exonic expression differences between castes. Previous research using honeybees did find an association between methylation and caste specific alternative splicing. Methylation differences between queens and workers in *A. mellifera* have been associated with caste specific splicing events (Lyko *et al.*, 2010). Additionally a knock-down of *Dnmt3* by RNA interference was found to affect alternative splicing patterns in *A. mellifera*, with decreased methylation levels being directly related to exon skipping and intron retention (Li-Byarlay *et al.*, 2013). However, another social insect species, the primitively social wasp, *Polistes dominula*, has also shown no direct association between methylation and alternative splicing (Standage *et al.*, 2016). However, this species shows extremely low genome methylation and appears to lack the *Dnmt3* gene responsible for *de novo* methylation, suggesting that the link between methylation and alternative splicing in insects is variable.

Exon methylation has been shown to play a role in histone modifications and nucleosome stability in mammals (Jones, 2012; Singer *et al.*, 2015). These modifications have the ability to affect alternative splicing patterns through RNA polymerase accessibility,

meaning whilst changes in DNA methylation may not be observed as directly related to alternative splicing, it's possible these changes have a downstream effect leading to transcriptional changes (Hunt *et al.*, 2013). The analysis of the relationship between methylation and alternative splicing done here could be elaborated on further to include non-caste specific splicing sites and to also potentially identify the role of exon methylation in other epigenetic processes, which may themselves, lead to alternative splicing.

It is also worth noting other epigenetic mechanisms may play a role in caste determination, for example microRNAs have been associated with caste switching in *A. mellifera* (Ashby *et al.*, 2016). Additionally Simola *et al.* (2016) found histone acetylation differences between worker castes of *Camponotus floridanus*. They inhibited histone acetylation and found this caused the major worker caste to behave more like a minor worker. This same species has also been shown to have caste specific methylation profiles (Bonasio *et al.*, 2012). These examples indicate it is likely an interplay between multiple mechanisms that ultimately cause social insect caste differentiation, again supported by the fact we find no association between methylation and caste-specific alternative splicing.

My final prediction was that differentially methylated genes between worker *B. terrestris* castes would be similar to those found to be differentially methylated between *A. mellifera* reproductive castes if methylation was involved in caste determination in Hymenoptera; I did not find any putative orthologues in common. This supports the idea in Bewick *et al.* (2019) that methylation may not directly influence caste determination. However, the differentially methylated gene list obtained for *A. mellifera* used queen samples to represent the reproductive caste (Lyko *et al.*, 2010), whereas here reproductive worker samples were used, this could also explain the lack of agreement.

Considerably more experimental research is needed to better define the relationship between epigenetic processes and caste determination in social insects. Future work should focus on the consequences of experimental methylation removal or addition (Pegoraro *et al.*, 2017), as well as exploring additional epigenetic mechanisms to attempt to identify a full pathway leading to reproductive caste differences. For example, CRISPR

has recently been used to knockout two sex-determining genes in *A. mellifera* causing individuals to change gender (McAfee *et al.*, 2019). This technology has also been adapted to be able to change the methylation state of a given loci (Vojta *et al.*, 2016), allowing the possibility of exploring the function of methylation in specific genes.

Overall, I have found the *B. terrestris* methylome appears similar to some other holometabolous insects, in terms of overall levels and the relationship with gene expression. I found no genome-wide methylation differences between reproductive castes. However, we did find differentially methylated genes between reproductive castes, with GO terms enriched in many biological processes, including reproduction. These results combined with previous research, (Amarasinghe *et al.*, 2014), indicate an association between methylation and reproductive caste differences in *B. terrestris*. However, it is clear, owing to the lack of consistency between differentially methylated genes and differentially expressed genes, methylation is not directly responsible for the associated changes in gene expression leading to the different reproductive phenotypes in *B. terrestris*. Additionally the lack of similarity between differentially methylated genes between castes in *B. terrestris* and between castes in *A. mellifera* suggest methylation may not directly contribute to caste determination in some Hymenoptera. Future work should focus on the experimental manipulation of epigenetic processes, such as methylation, in social insects in order to clarify functional roles within and across species.

Chapter 3

Allele-specific methylation in reproductive and sterile bumblebee workers.

Hollie Marshall, Zoë Lonsdale and Eamonn Mallon.

3.1 Abstract

Allele-specific expression is when one allele of a gene shows higher levels of expression compared to the other allele, in a diploid organism. Genomic imprinting is an extreme example of this, where some genes exhibit allele-specific expression in a parent-of-origin manner. Recent work has identified potentially imprinted genes in two species of Hymenoptera. However, the molecular mechanism which drives this allelic expression bias remains unknown. In mammals DNA methylation is often associated with imprinted genes. DNA methylation systems have been described in species of Hymenoptera, providing a candidate imprinting mechanism. Using previously generated RNA-Seq and whole genome bisulfite sequencing from reproductive and sterile *B. terrestris* workers I have identified genome-wide allele-specific expression and allele-specific DNA methylation. The majority of genes displaying allele-specific expression are common between reproductive castes and the proportion of allele-specific expression bias generally varies between colonies. This study has also identified allele-specific methylation differences between reproductive castes and found there is no significant overlap of genes showing allele-specific expression and allele-specific methylation. These results indicate that DNA methylation does not drive genome-wide allele-specific expression in this species. It may be that DNA methylation is just one of a number of epigenetic factors acting in *trans* to direct gene expression patterns. The relationship between DNA methylation and open chromatin regions would help to elucidate this relationship. Additionally, only a small number of the genes identified may be 'imprinted' and it may be these genes which are associated with allele-specific DNA methylation. Future work utilising reciprocal crosses to identify parent-of-origin DNA methylation will further clarify the role of DNA methylation in parent-of-origin allele-specific expression.

3.2 Introduction

Allele-specific expression is when one allele of a gene shows higher levels of expression compared to the other allele, in a diploid organism. Unlike genetic dominance, allele-specific expression can be tissue specific and/or caused by epigenetic modifications, independent of the underlying genotype. It has been associated with genomic mechanisms such as X-chromosome inactivation and genomic imprinting, i.e. parent-of-origin allele-specific expression (Knight, 2004). It has been predicted that social insects should display imprinted genes (Queller, 2003) based on assumptions of the kinship theory (Haig, 2000). Recent research has identified parent-of-origin allele-specific expression in honeybees (Galbraith *et al.*, 2016b; Kocher *et al.*, 2015), with one study identifying greater paternal-allele (patrigene) expression bias in reproductive workers compared to sterile workers, as predicted by the kinship theory (Galbraith *et al.*, 2016b). However, the mechanism by which these genes exhibit this expression bias remains unknown.

In mammals and angiosperm plants imprinted genes are often associated with allele-specific DNA methylation (Barlow and Bartolomei, 2014) and occasionally with histone modifications (Inoue *et al.*, 2017). Many social insects have functional DNA methylation systems, including the honeybee (Bewick *et al.*, 2016; Lyko *et al.*, 2010), which also exhibits genes with allele-specific expression. However, the function of DNA methylation in insects remains debated (Glastad *et al.*, 2018).

Various studies have found an association between methylation and gene expression (Glastad *et al.*, 2014; Bonasio *et al.*, 2012; Patalano *et al.*, 2015, Chapter 2), and alternative splicing (Lyko *et al.*, 2010; Glastad *et al.*, 2016) in social insects. However, this is not uniform across all social species (Standage *et al.*, 2016). Additionally, allele-specific expression has been associated with allele-specific methylation in two ant species, *Camponotus floridanus* and *Harpegnathos saltator* (Bonasio *et al.*, 2012). Another study did not find any relationship between allele-specific expression and methylation in a hybrid cross of two non-social wasp species, *Nasonia vitripennis* and *Nasonia giraulti* (Wang *et al.*, 2016). These results support the general hypothesis that imprinted genes exist specifically in social insect species (Queller, 2003) and also suggest that DNA methy-

lation could serve as the imprinting mark.

Bumblebees provide an ideal system to further investigate the relationship between allele-specific methylation and allele-specific expression, specifically with a view of elucidating potential mechanisms involved in genomic imprinting in social insects. Using a candidate gene approach, previous research identified allele-specific expression in a gene (ecdysone 20-monoxygenase-like) related to worker reproductive behaviour in *B. terrestris* (Amarasinghe *et al.*, 2015). Additional research has since used RNA-seq data to identify >500 loci showing allele-specific expression throughout the *B. terrestris* genome (Lonsdale *et al.*, 2017). This same study also identified 19 genes displaying allele-specific expression and allele-specific methylation, although this was in a single individual (Lonsdale *et al.*, 2017).

It is predicted that imprinted genes in *B. terrestris* will specifically have a role regarding worker reproductive behaviour (Queller, 2003). Methylation has been directly associated with reproductive behaviour in *B. terrestris* (Amarasinghe *et al.*, 2014) and recent research has identified differentially methylated genes between reproductive and sterile castes (Chapter 2).

Whole genome bisulfite sequencing and RNA-seq from reproductive and sterile workers, spanning three genetically distinct colonies, were used to investigate allele-specific expression and allele-specific methylation in *B. terrestris*. I hypothesise that if genomic imprinting plays a role in worker reproductive behaviour in *B. terrestris*, genes showing allele-specific expression will be enriched for reproductive processes. Additionally, if DNA methylation acts as an imprinting mark in *B. terrestris*, a direct association between allele-specific expression and allele-specific methylation will be found.

3.3 Methods

3.3.1 Data generation

The data used for this study were generated in Chapter 2, see sections 2.3.1 and 2.3.2.

3.3.2 Identification of allele-specific expression

Data were quality checked using fastqc v.0.11.5 (Andrews, 2010) and trimmed using CutAdapt v1.1 (Martin, 2011). Trimmed data were aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1 (Sadd *et al.*, 2015)) using STAR v2.5.2 (Dobin *et al.*, 2016) with standard parameters. SNPs were then called per sample following the ‘GATK best practices for SNP calling from RNA-Seq data’ pipeline (Auwera, 2014). Briefly this involves assigning read groups and marking duplicate reads using Picard v.2.6.0 (Broad Institute, 2018), removing reads overlapping introns to keep only exonic reads, calling SNPs with a minimum confidence score of 20.0, then filtering SNPs by windows of three within a 35bp region, to keep only those with a Fisher strand value greater than 30.0 and a quality by depth value greater than 2.0 (these filtering steps are considered particularly stringent) (Auwera, 2014). SNPs were then filtered to keep only biallelic SNPs and reads were then counted per SNP using the ‘ASEreadcounter’ program from GATK.

A custom R script was used to annotate the SNP positions with gene identifiers, SNPs were filtered to remove those with a coverage of less than 10. SNPs were also removed if they had a count of zero for either the alternative or reference SNP as they may have been mis-called by the SNP caller as heterozygous when they are actually homozygous. Two new columns were then created to represent each allele, as it is not possible to tell which SNPs belong to which allele (e.g. a reference SNP at a given position may be accompanied with an alternative SNP on the same allele). The counts for each SNP were then allocated to either ‘allele: 1’ or ‘allele: 2’, with the highest counts per SNP allocated to ‘allele: 1’, Table 3.1. Counts per SNP per allele were then summed over each gene for each reproductive status per colony creating one representative sample per reproductive status per colony.

Table 3.1: Example of how the counts per SNP were allocated to assumed alleles.

Chromosome	SNP	Ref Count	Alt Count	Allele 1	Allele 2
NC_015762.1	265980	11	11	11	11
NC_015762.1	276809	23	25	25	23
NC_015762.1	276870	24	21	24	21
NC_015762.1	277048	36	34	36	34
NC_015762.1	278272	19	23	23	19

As this method is naive to allele specific alternative splicing, stringent filtering was applied throughout. Only genes with counts found in every reproductive status in each colony were considered for allele specific expression analysis. A logistic regression model was then applied with the proportion of allelic expression per gene as the dependent variable and with reproductive status and colony as independent variables, a quasibinomial distribution was applied to account for any overdispersion within the data. P-values were corrected for multiple testing using the Benjamini-Hochberg method (Benjamini and Hochberg, 1995) and genes were classed as showing allele specific expression if the adjusted p-value was <0.05 and the average proportion of allelic expression across colonies was >0.7 . This stringent filtering was used to account for the possible mis-allocation of SNPs to the correct alleles and to account for differences in genomic *cis*-effects across colonies.

3.3.3 Identification of allele-specific methylation

Data were quality checked using fastqc v.0.11.5 (Andrews, 2010) and trimmed using CutAdapt v1.1 (Martin, 2011). Trimmed data were aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1, (Sadd *et al.*, 2015)) using Bismark v.0.16.1 (Krueger and Andrews, 2011) and bowtie2 v.2.2.6 (Langmead and Salzberg, 2012) with standard parameters. Alignment output files were deduplicated using Bismark v.0.16.1 (Krueger and Andrews, 2011) and sorted and indexed using samtools v.1.3.2 (Li *et al.*, 2009).

Allele-specific methylation was determined using a probabilistic model implemented using the ‘amrfinder’ program from the MethPipe package v.3.4.2 (Fang *et al.*, 2012). This program scans the genome using a sliding window approach and fits two models

to each interval, one model predicts the methylation levels of each window are the same for both alleles and a second model predicts the methylation levels are different for each allele. The likelihood of the two models is then compared and a false discovery rate corrected p-value is generated per window (Fang *et al.*, 2012). Sample input files were merged by reproductive group in order to increase the coverage per CpG as this method does not take replication into account. Windows were defined as three CpGs with a minimum coverage of 10 reads each. Only regions within the main 18 linkage groups of the *B. terrestris* genome were tested for allele specific methylation as the program is not designed to cope with the number of unplaced scaffolds (5,591) that the current genome build contains. Finally, allelically methylated regions falling within a gene were annotated with the gene identifier using a custom R script.

This method of identifying allelically methylated regions is preferable compared to using SNP data to identify alleles for the data presented here. Firstly, it is difficult to call SNPs reliably from bisulfite data, this is because C/T SNPs and C/T conversions introduced during bisulfite treatment appear the same within the data (Liu *et al.*, 2012). Secondly, as the samples used were pooled females, each sample may contain multiple SNPs at a given locus meaning the coverage produced per SNP would be too low to produce any reliable estimates of allelic methylation.

3.3.4 Gene ontology enrichment

Gene ontology terms for *B. terrestris* were taken from a custom database made in Bebane *et al.* (2019). GO enrichment analysis was carried out using the hypergeometric test with Benjamini-Hochberg (Benjamini and Hochberg, 1995) multiple-testing correction, $q < 0.05$. GO terms from genes showing allele-specific expression were tested for enrichment against a database made from the GO terms of all genes identified in the RNA-Seq data. GO terms from genes showing allele-specific methylation were tested for enrichment against a database made from the GO terms of all genes identified as methylated from the BS-Seq data set. Descriptions of GO terms and treemaps were generated by REVIGO (Supek *et al.*, 2011).

3.3.5 Comparative analyses

Significant overlap between genes showing allele-specific expression and allele-specific methylation was tested using a hypergeometric test. Overlap plots were generated using the *UpSetR* package in R (Lex *et al.*, 2016). Custom R scripts were used to test for a relationship between allele-specific expression and allelically methylated genes and the interaction of that relationship with reproductive caste.

All bioinformatic scripts used within this chapter can be found at: <http://doi.org/10.5281/zenodo.1974852>.

3.4 Results

3.4.1 Allele specific expression

All reads had 13bp trimmed from the start due to base bias generated by the Illumina protocol (Krueger *et al.*, 2011). The mean number of uniquely mapped reads was $89.4\% \pm 0.8\%$ (mean \pm standard deviation). This equated to a mean of $10,115,366 \pm 1,849,600$ uniquely mapped reads (supplementary 3.0.0). The average number of heterozygous SNPs called per sample was $32,604 \pm 4,983$, of which an average of $18,930 \pm 3,594$ had a coverage greater than 10 and after filtering to remove potentially homozygous SNPs the average final number of SNPs per sample was $16,631 \pm 3,135$ (Fig. 3.1a). The average number of genes with at least one SNP per sample was $3,597 \pm 514$ (Fig. 3.1b). Sample J8_24 was removed from all downstream analyses as it was potentially incorrectly labelled, see Chapter 2, section 2.3.5. Sample J8_18 was also removed from all downstream analyses due to the considerably lower number of SNPs obtained. Given that genes must occur in every sample to be used, keeping this sample would have greatly reduced the number of genes available to test. Upon data inspection, it is likely there were considerably less SNPs called in this sample as the sequencing depth was considerably lower than all other samples, with 3,354,181 uniquely mapped reads compared to the mean of $>10,000,000$, as stated above.

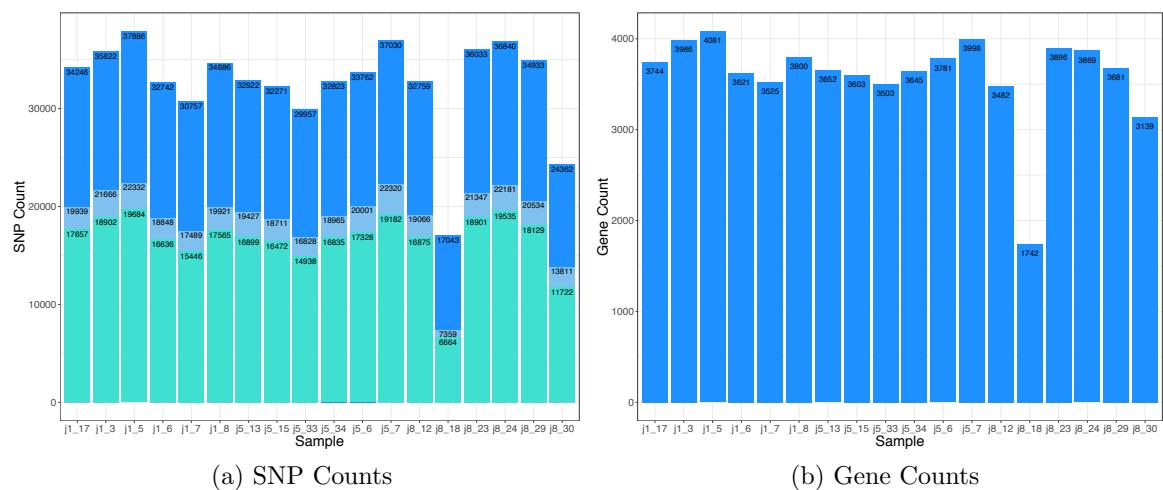

Figure 3.1: (a) Component bar chart showing the total number of SNPs called per *Bombus terrestris* sample, the number of which have a minimum coverage of 10 and of those which have coverage for both alternate and reference alleles. (b) The number of genes per sample which have at least one SNP present. The sample names represent the unique colony (j1, j5 or j8) and the individual number.

Only genes present in all conditions (colony and reproductive status) were tested for allele-specific expression, this lead to a final conservative list of 2,489 genes (22.6% of all annotated genes in the reference genome Bter_1.0). A total of 98 genes were found to show significant allelic expression bias (adjusted $p < 0.5$ and average allelic expression proportion >0.7) (Fig. 3.2, supplementary 3.0.1).

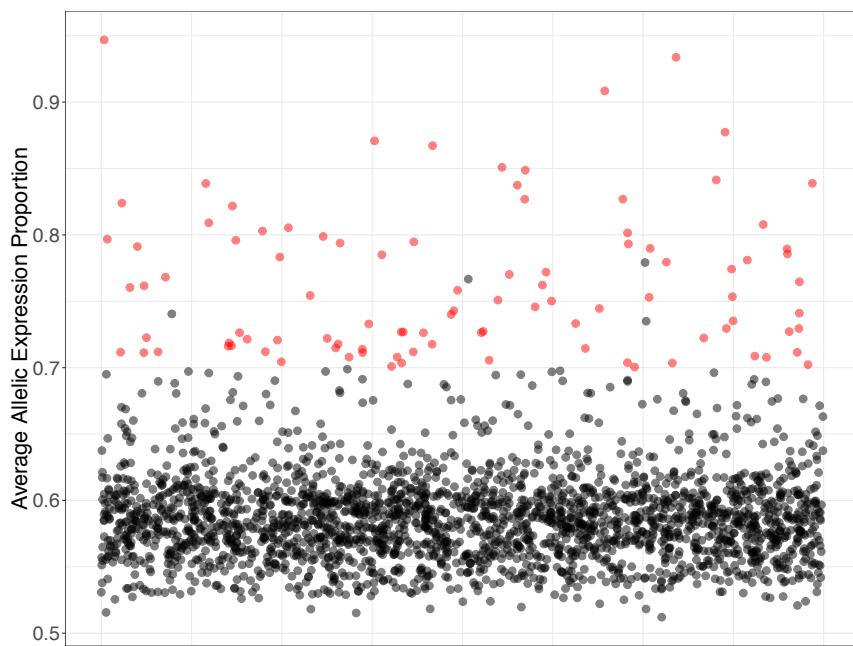

Figure 3.2: Spread of allelic ratios averaged across all *Bombus terrestris* colonies and reproductive samples. Each dot represents a gene ($N = 2,489$), the red dots show genes showing significant allelic expression bias (adjusted $p < 0.05$ and average allelic expression proportion > 0.7).

The genes of reproductive and sterile workers show similar levels of allelic expression (Spearman's rank correlation, $S = 790780000$, $\rho = 0.6922959$, $p < 0.000$, Fig. 3.3a). Of the 98 genes found to show allele specific expression a significant number are shared between reproductive and sterile workers (hypergeometric test $p = < 0.000$, Fig. 3.3b), with five found only in sterile workers and one found only in reproductive workers, (Fig. 3.4). There is also some variability in allelic expression proportion between colonies (Fig. 3.5).

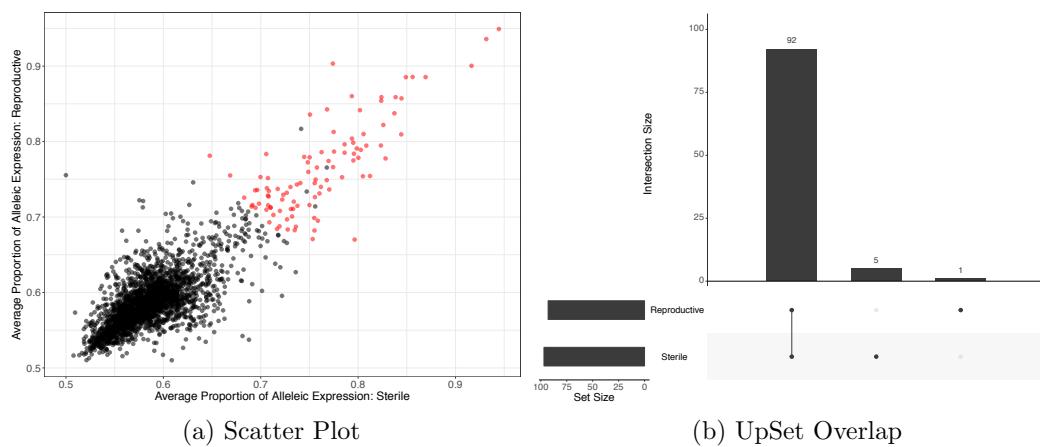

Figure 3.3: (a) Scatter plot showing the allelic expression proportion of *Bombus terrestris* sterile workers plotted against the allelic expression proportion of reproductive workers (allelic expression proportion averaged across colonies). Each point is a gene ($N = 2,489$), the red points indicate genes showing significant allele specific expression (adjusted p-value <0.05 and average allelic expression proportion >0.7). (b) An UpSet plot showing the number of allelically expressed genes shared by reproductive status and the number unique to reproductive or sterile workers. The set size indicates the number of genes in each category. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list.

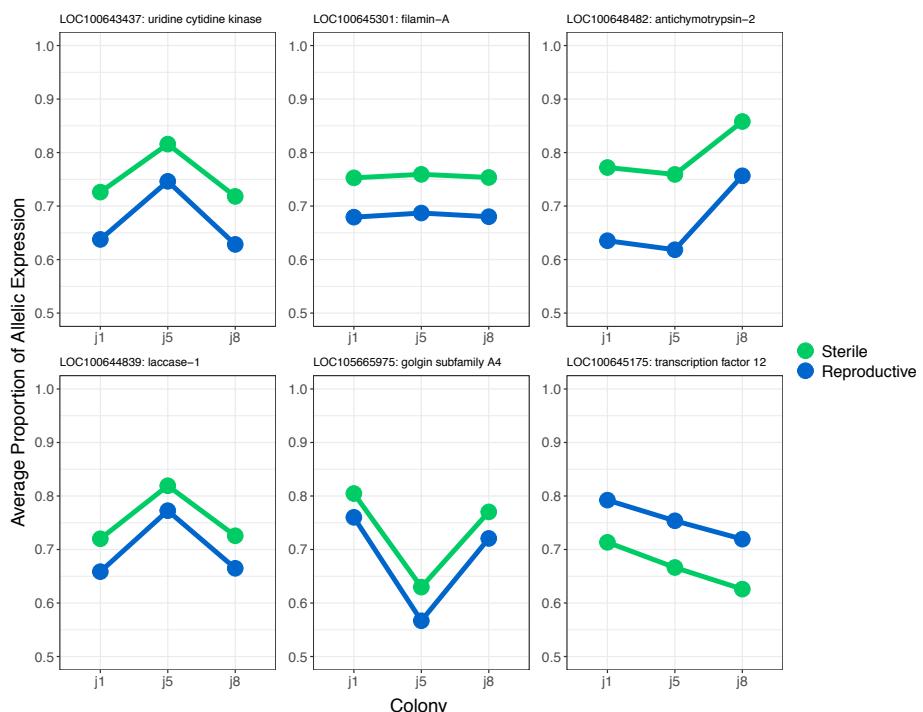

Figure 3.4: The average proportion of allelic expression for genes found to show significant allele specific expression in only sterile or reproductive *Bombus terrestris* workers.

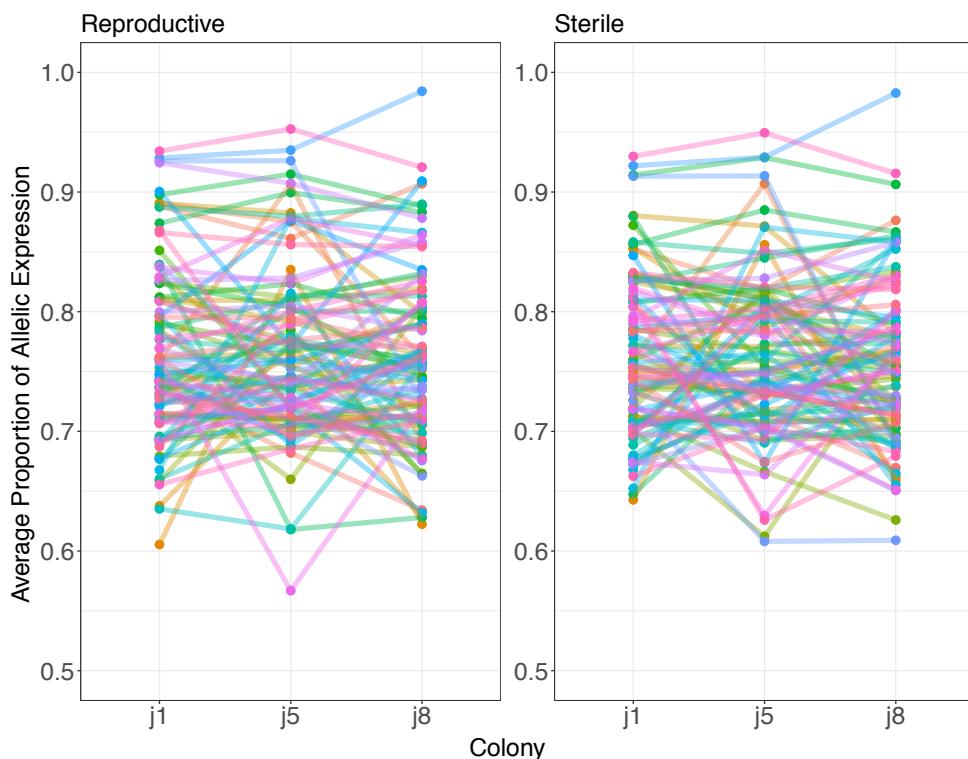

Figure 3.5: The average proportion of allelic expression for reproductive and sterile *Bombus terrestris* workers across each colony. Each colour represents a unique gene ($N = 98$). Genes shown are those deemed to show significant allele-specific expression ($q < 0.05$ and average proportion of expression bias > 0.7).

Enriched GO terms associated with genes showing significant allele specific expression were involved in multiple biological processes, including: *female gamete generation* (GO:0007292), *positive regulation of ovulation* (GO:0060279) and *positive regulation of histone H3-K9 methylation* (GO:0051574), supplementary 3.0.2.

GO terms enriched for the five genes showing allele specific expression in sterile workers also included a variety of biological processes, for example *determination of adult lifespan* (GO:0008340). The GO terms enriched for the single gene showing allele specific expression in reproductive workers included: *ovarian follicle cell development* (GO:0030707) and *female gamete generation* (GO:0007292), supplementary 3.0.2. These results should be interpreted with care as the gene lists are relatively small. However, it is worth noting that the hypergeometric test used to generate the enriched terms has been previously shown to be the most appropriate statistic for gene ontology enrichment for small gene lists (Rivals *et al.*, 2007).

3.4.2 Allele specific methylation

Up to a maximum of 10bp were trimmed from the start of all reads due to base bias generated by the Illumina sequencing protocol (Krueger *et al.*, 2011). The mean mapping efficiency was $63.6\% \pm 1.4\%$ (mean \pm standard deviation) and the mean coverage was 17.7 ± 0.5 reads per base, the average number of uniquely mapped reads were $27,709,214 \pm 753,203$ (supplementary 3.0.3). 12.79% of genome was not tested for allele-specific methylation as only regions in the main 18 linkage groups of the *B. terrestris* genome (Bter_1.0) could be tested.

Reproductive workers have significantly more allelically methylated regions compared to sterile workers, 303 (supplementary 3.0.4) compared to 201 (supplementary 3.0.5) respectively (Chi-squared goodness of fit; X-squared = 20.643, df = 1, p <0.000). The majority of these regions occur within annotated genes, 26 and 15 allelically methylated regions occur outside of a gene for reproductive and sterile workers respectively.

Most allelically methylated genes are unique to either sterile or reproductive workers. However, there is a significant number of common allelically methylated genes (hypergeometric test p <0.000, Fig. 3.6a). Most allelically methylated regions found within genes do not have additional annotation. However, there are more located in exons compared to introns for both reproductive and sterile castes (Fig. 3.6b).

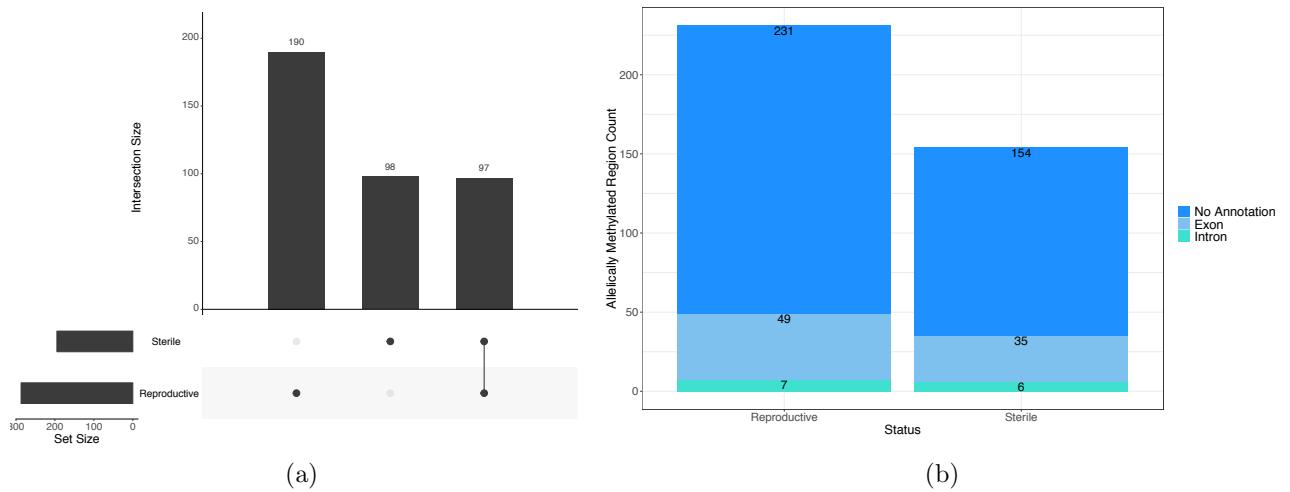

Figure 3.6: (a) UpSet plot showing the number of genes with allele specific methylation in just reproductive and sterile *Bombus terrestris* workers, as well as the number of genes in common between both reproductive castes. The set size indicates the number of genes in each category. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list. (b) Component bar plot showing the number of allelically methylated regions (within genes), found in exons and introns and the number without additional annotation.

Enriched GO terms associated with allelically methylated genes in both castes are involved in a variety of biological processes with many relating to the term *positive regulation of RNA splicing* (GO:0033120). As above, the enriched GO terms associated with allelically methylated genes in just sterile or reproductive workers are also involved in a large number of biological processes. However, the terms *oocyte development* (GO:0048599), *ovarian follicle development* (GO:0001541), *oogenesis stage* (GO:0022605) and other reproductive terms were enriched in allelically methylated genes of reproductive workers. Additionally none of these terms were identified in the GO terms associated with the allelically methylated genes of sterile workers (supplementary 3.0.6).

3.4.3 Relationship of allele specific expression and methylation

There is no significant overlap between genes showing allele specific expression and allele specific methylation (overlap between all conditions; hypergeometric test $p = 0.055$, overlap between allele specific expression and allele specific methylation in reproductive workers; hypergeometric test $p = 0.519$, Fig. 3.7). However, six genes were found to show allele specific methylation and expression in both reproductive castes and one gene was found to show allele specific expression in both castes and allele specific methylation in reproductive workers (Table 3.2).

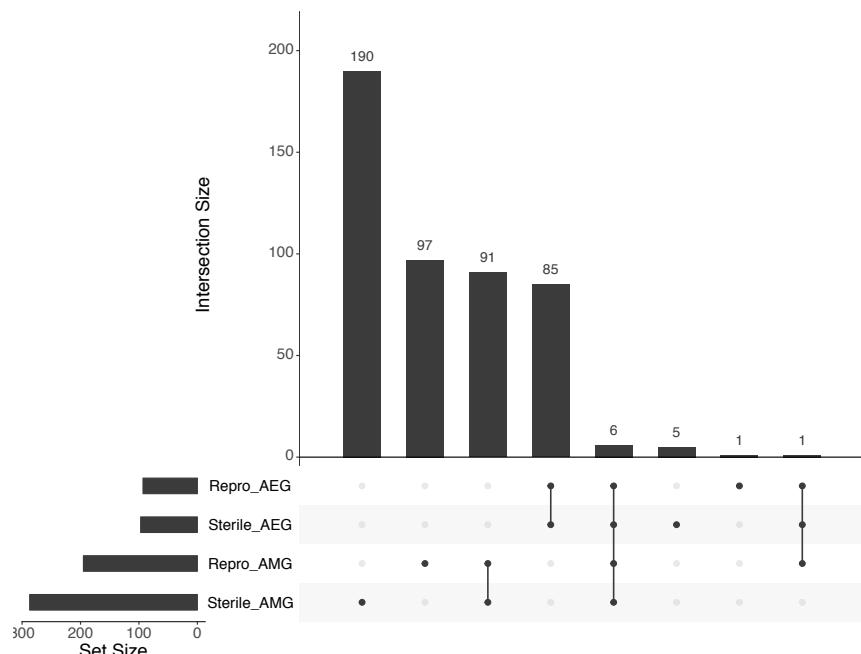

Figure 3.7: (a) UpSet plot showing the overlapping genes identified as allelically methylated and/or allelically expressed in both *Bombus terrestris* castes. The set size indicates the number of genes in each category. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list.

Table 3.2: Genes identified as showing allele specific methylation and expression in both reproductive castes. * this gene does not show allele specific methylation in sterile workers.

Gene ID	Gene Description
LOC100643777	40S ribosomal protein S6
LOC100643807	protein Jumonji
LOC100645564	peripheral plasma membrane protein CASK
LOC100651252	ATP-dependent RNA helicase WM6
LOC100652132	importin-11
LOC105666051	uncharacterized
LOC105666711*	tyrosine-protein kinase Btk29A*

The GO terms enriched for the genes found to be allelically methylated and expressed (Table 3.2) compared to the entire genome as background, included multiple biological processes (supplementary 3.0.7). Specifically various reproductive related terms were enriched; *multi-organism reproductive behaviour* (GO:0044705), *female gamete generation* (GO:0007292) and *germ cell development* (GO:0007281).

There is a significant difference in the proportion of allelic expression of genes allelically methylated in either reproductive workers, sterile workers or both (Kruskal-Wallis; chi-squared = 30.103, df = 2, p <0.000). Genes allelically methylated in both castes show on average higher levels of allele specific expression compared to those unique to either reproductive or sterile workers (Dunn test with Benjamin-Hochberg correction; both compared to unique in reproductive workers Z = 5.445, q <0.000, both compared to unique in sterile workers Z = 3.621, q <0.000), Fig. 3.8. Additionally, genes with allele specific methylation unique to reproductive workers show lower levels of allele specific expression compared to genes with allele specific methylation unique to sterile workers (Dunn test with Benjamin-Hochberg correction; reproductive compared to sterile Z = -2.688, q <0.000), Fig. 3.8. Finally, there is no interaction between reproductive caste and allele specific expression proportion on the allelic methylation status of a gene (Anova, interaction vs main effects model, $F^{2, 255} = 0.0114$, p = 0.988), Fig. 3.8.

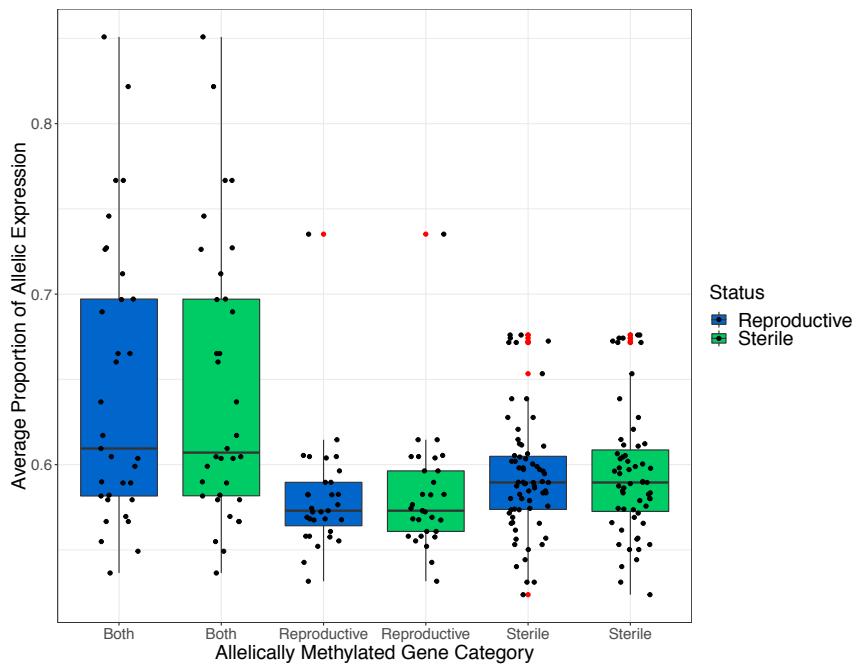

Figure 3.8: Boxplots showing the proportion of allele specific expression in reproductive and sterile *Bombus terrestris* workers for genes identified as allelically methylated in either both castes, just reproductive workers or just sterile workers. Each boxplot shows the median along with the 25th and 75th percentile. The whiskers represent 1.5X the interquartile range. Outliers are represented as additional red points and each gene is represented by a black dot. Allelically methylated in both castes = 33. Allelically methylated genes in reproductive workers = 29 and in sterile workers = 57.

All bioinformatic scripts used within this chapter can be found at: <http://doi.org/10.5281/zenodo.1974852>.

3.5 Discussion

Using whole genome bisulfite sequencing and RNA-seq from reproductive and sterile *B. terrestris* workers from three independent colonies I have identified genome wide allele-specific expression and allele-specific methylation. The majority of genes displaying allele-specific expression are common between reproductive castes and the proportion of allele-specific expression generally varies between colonies. This study has also identified allele-specific methylation differences between reproductive castes and found the majority of allelic-methylation events are located within genes. However, there is no significant overlap of genes showing allele-specific expression and allele-specific methy-

lation. I have also found that genes with common allele-specific methylation between castes show a higher proportion of allelic-expression bias compared to allelically methylated genes unique to either reproductive or sterile workers.

This study has identified 98 genes which show allele-specific expression from a stringent subset of genes covering 22% of all annotated genes within the *B. terrestris* genome. This number is in line with previous research that identified around 500 loci across the whole genome of *B. terrestris* (Lonsdale *et al.*, 2017). Predictions based on the kinship theory suggest if imprinted genes exist in social insects, such as *B. terrestris*, they will be involved in worker reproductive behaviour (Queller, 2003). GO terms enriched for the allelically expressed genes were involved in reproductive processes, additionally the single gene showing allele-specific expression in only reproductive workers is involved in female reproduction. These findings support the idea that if imprinted genes are present in *B. terrestris* some will be involved in worker reproductive behaviour.

The proportion of allelic expression bias differed between colonies and the GO terms enriched for all allelically expressed genes, whilst containing reproductive terms, were varied. This indicates allele-specific expression may be involved in other mechanisms, rather than solely imprinting, and that it plays a diverse role in *B. terrestris*. Previous research identified 61 genes showing allele-specific expression in a cross of two *Nasonia* species, the expression bias in all genes was attributed to *cis*-effects (Wang *et al.*, 2016). There have also been a number of non-imprinted loci found in humans which show allele-specific expression directly associated with *cis*-acting polymorphic sites, such as single nucleotide polymorphisms (SNPs) (Tycko, 2010). Given that each colony used here is genetically distinct, *cis*-effects, such as SNPs, are likely represented in the results. In humans <1% of genes are imprinted but considerably more exhibit allele-specific expression (Tycko, 2010), it is therefore reasonable to assume only a small percentage of the genes identified as showing allele-specific expression in this study may actually be imprinted genes.

Whilst the majority of genes showing allele-specific expression were common between reproductive castes, a large number of genes show allele-specific methylation which are unique to either reproductive or sterile workers. Additionally, there are significantly

more allelically-methylated sites in reproductive workers compared to sterile workers, with allelically methylated genes in reproductive workers enriched for GO terms related to reproduction. These findings support previous research which suggests methylation is associated with worker reproductive behaviour. Amarasinghe *et al.* (2014) found a global erasure of DNA methylation increased reproductive behaviour, Liu *et al.* (2018) found differences in expression in genes responsible for methylation between castes and Chapter 2 found differentially methylated genes between *B. terrestris* castes, some of which were involved in reproductive processes. Numerous other studies have linked methylation to caste differences in various other social insect species, such as: *Apis mellifera* (Lyko *et al.*, 2010; Elango *et al.*, 2009), *Camponotus floridanus* and *Harpegnathos saltator* (Bonasio *et al.*, 2012), *Polistes dominula* (Weiner *et al.*, 2013) and *Zootermopsis nevadensis* (Glastad *et al.*, 2016). The development of experimental techniques to alter DNA methylation, such as CRISPR/Cas (Vojta *et al.*, 2016), will allow for experiments to test the causal effect of DNA methylation and allele-specific methylation on caste determination in social insects.

It is clear from this study that DNA methylation does not play a direct causal role in the production of all allele-specific expression events, with only a small number of genes displaying both allele-specific expression and methylation. This does not rule out the possibility that methylation may act as an imprinting mark, if only a small number of genes are actually imprinted, as in humans (Tycko, 2010). GO terms enriched for the few genes which do show allele-specific methylation and allele-specific expression include reproductive related terms. As theory predicts imprinted genes should affect reproduction in *B. terrestris* (Queller, 2003), the identification of these genes provides the groundwork for future research to further investigate the possibility of parent-of-origin methylation as an imprinting mark.

Additional imprinting marks should not be ruled out as GO terms enriched for genes showing allele-specific methylation included histone modifications. Genes displaying allele-specific methylation may feed into other mechanisms which may, in-turn, drive allele-specific expression, accounting for the lack of direct association. For example, methylation can signal histone modifications which create condensed chromatin, silencing many genes in one region (Barlow, 2011), this process can also occur in an

allele-specific manner (Tycko, 2010).

Whilst only a small number of genes show allele-specific methylation and allele-specific expression, genes showing allele-specific methylation in both reproductive castes had higher allelic expression bias compared to those found only in one caste. One explanation is that allelically methylated genes present in both castes carry out different functions to those identified in a single caste. This is supported by the diverse GO terms obtained for shared and caste-specific allelically methylated genes. In humans, the majority of allele-specific methylation is genotype dependent rather than parentally inherited (Meaburn *et al.*, 2010). Whereas, allele-specific methylation associated with imprinting is known to change at different stages of development (Edwards *et al.*, 2017). It may therefore be that the common allelically methylated genes identified here are linked to genotype (i.e. epialleles) whereas the caste-specific allelically methylated genes may represent imprinting marks.

In order to further understand the role and origin of allele-specific methylation a pipeline is needed which integrates SNP data (generated from genomic DNA), to allow the identification of specific alleles. Using this method rather than the probabilistic models employed here would enable hyper/hypomethylation (i.e. higher or lower methylation in one conditions compared to another) to be associated with allele-specific expression when they occur in tandem. Additionally, this method, with increased biological replication per colony, would facilitate the identification of epialleles, i.e. when allele-specific methylation is driven by genotype. Epialleles have been identified in the honeybee (Wedd *et al.*, 2016) and will be important in the identification of parent-of-origin methylation (Remnant *et al.*, 2016).

Overall, this study provides additional evidence suggesting imprinted genes exist in *B. terrestris* and are related to worker reproductive behaviour as predicted by Queller (2003) and Haig (2000). However, the role of DNA methylation, as a mechanism of potential imprinting, is still unclear. The diverse function of genes showing allele-specific expression and/or allele-specific methylation suggests a varied role for these genomic mechanisms and experimental validation of their function is required. Future research utilising highly related reciprocal crosses, in order to identify the parental

origin of an allele, is needed to discover imprinted genes and to take into account *cis*-effects, such as genotype. These types of crosses can also be used to further investigate DNA methylation as a mechanism of imprinting.

Chapter 4

Reciprocal crosses and RNA-seq to explore genomic imprinting in the bumblebee, *Bombus terrestris*.

Hollie Marshall, Jelle Van Zweden, Kristof Benaets, Felix Wäckers, Tom Wenseleers and Eamonn Mallon.

4.1 Abstract

Genomic imprinting is the expression bias of one allele in a diploid organism, expression being dependent upon which parent the allele was inherited from. Haig's kinship theory predicts that genomic imprinting occurs due to an evolutionary conflict-of-interest between the matrigenes (maternal alleles) and patrigenes (paternal alleles) of an individual. In social insects, it has been suggested that genomic imprinting should be widespread, since relatedness asymmetries within the colony would be expected to lead to many conflicts-of-interest between matrigenes and patrigenes. One recent study identified parent-of-origin gene expression in honeybees and found evidence supporting one prediction of Haig's kinship theory. However very little is known about genomic imprinting in Hymenoptera, and insects in general, and multiple theoretical predictions must be tested to avoid single-study confirmation bias. In the present investigation, I therefore decided to test if parent-of-origin gene expression also occurs in another social bee, the bumblebee *Bombus terrestris*. Four family-wise reciprocal crosses between the subspecies, *B. terrestris audax* and *B. terrestris dalmatinus* were carried out. Whole genome sequencing of the parents and RNA-seq of the offspring allowed the identification of parent-of-origin gene expression. I found equal numbers of maternally and paternally expressed alleles in both reproductive and sterile workers with the majority of genes showing the same expression bias in both castes. There was very little overlap of differentially expressed genes between reproductive worker castes and genes showing parent-of-origin expression. I also found low evolutionary conservation of potentially imprinted genes in Hymenoptera, with only two homologous genes showing parent-of-origin expression in *B. terrestris* and *A. mellifera* suggesting rapid evolution of imprinted genes in this class. Additionally this study highlights the importance of using many species to test multiple predictions in the evaluation of evolutionary theories. Future work exploring epigenetic imprinting mechanisms and the function of genes showing parent-of-origin expression is needed.

4.2 Introduction

Genomic imprinting is the expression of only one allele in a diploid organism, expression being dependent upon which parent the allele was inherited from, i.e. parent of origin-dependent gene expression (Rodrigues and Zilberman, 2015). Multiple evolutionary theories attempt to explain its existence (reviewed in Patten *et al.*, 2014). The most widely accepted explanation is the kinship theory developed by Haig (2000). This theory predicts genomic imprinting arose due to natural selection acting differently on the matrigenes (maternal alleles) and the patrigenes (paternal alleles) of an individual for given processes. For example; in a polyandrous mating system with maternal care, patrigenes are predicted to be subject to selection pressures which increase resource allocation from the mother at the expense of siblings. Matrigenes in this scenario are predicted to be selected for equal resource distribution amongst offspring.

The majority of support for this theory comes from studies based on mammal and flowering plant systems (Patten *et al.*, 2014). However, it has been suggested haplodiploid social insects can provide an ideal system to independently test Haig's kinship theory (Queller, 2003). Colonies of social bees consist of diploid females (queens and workers) and haploid males created from unfertilised eggs. This haplodiploidy results in workers which all share the full paternal genome, when queens are singly mated. In this scenario the kinship theory (Haig, 2000) predicts patrigenes should be under stronger selection for general care-giving compared to matrigenes. However, when queens mate with multiple males, workers are more likely to have higher maternally derived relatedness and the predictions reverse (Queller, 2003).

Genomic imprinting in mammals and plants is mediated via methylation marks in many cases, with higher promotor methylation generally associated with transcriptional silencing of one allele (Scott and Spielman, 2006; Li *et al.*, 2003; Satyaki and Gehring, 2017). Multiple social insects are known to possess fully functional methylation systems (Glastad *et al.*, 2015). Methylation in social insects is enriched in gene bodies with possible implications in alternative splicing (Li-Byarlay, 2016; Lyko *et al.*, 2010) and is associated with highly expressed genes, such as housekeeping genes (Glastad *et al.*,

2011, 2013; Hunt *et al.*, 2010). Whilst displaying some differences and some similarities to both plant and mammal methylation systems (Li-Byarlay, 2016; Feng *et al.*, 2010), methylation in social insects provides a possible mechanism for producing parent-of-origin gene expression.

To date the majority of research exploring parent-of-origin effects in social insects has focused on the behavioural and physiological outputs of genetic crosses and in only two species. In the Argentine ant (*Linepithema humile*) paternal effects were observed in care-giving associated behaviours and in sex allocation of offspring (Libbrecht and Keller, 2012; Libbrecht *et al.*, 2011). Paternal effects on dominance and stinging behaviour have also been observed in crosses of European and Africanized honeybees (Guzman-Novoa *et al.*, 2005). Additionally Oldroyd *et al.* (2014) found a parent-of-origin effect on increased ovary size in honeybees but could not definitively determine which parent this effect was driven by.

More recently, reciprocal crosses and next generation sequencing technologies have been used to identify genes with parent-of-origin expression patterns in honeybees. Kocher *et al.* (2015) and Galbraith *et al.* (2016b) both used RNA-Seq to study parent-of-origin gene expression in hybrid crosses of honeybee sub-species. Kocher *et al.* (2015) found a matrigenic bias in gene expression. However, it was later shown that sub-species incompatibility effects influenced the results obtained (Gibson *et al.*, 2015). Showing some support for the kinship theory, Galbraith *et al.* (2016b) found a greater patrigenic expression in reproductive workers compared to sterile workers, with increased patrigenic expression in the reproductive tissues. However, this study is limited to only one species and tests only one prediction from the many predictions made in Queller (2003) for how matrigenic/patrigenic expression bias may play a role in social insect colonies.

To test the robustness of Haig's kinship theory I present gene expression data of reproductive and sterile workers from reciprocal crosses of sub-species of the eusocial bumblebee, *Bombus terrestris*. This species is naturally singly-mated and as such the reproductive predictions for the presence of matrigenic/patrigenic expression bias are the reverse of those predicted for the naturally multiply-mated honeybee. As in Galbraith *et al.* (2016b) I also test the effect of queen-less conditions. Under queen-less

conditions matrigenes should be selected to favour individual worker reproduction as there is a higher likelihood they are present in the individual worker's offspring than in her nephews (Fig. 4.1). It is equally likely patrigenes will occur in the offspring of an individual worker and her nephews. Therefore, patrigenes should not experience selective pressure for reproductive behaviour or for sterile nursing behaviour as both are just as beneficial.

I have utilised RNA-seq libraries from reproductive workers and sterile workers, as well as whole genome sequencing libraries from both parents, in order to identify parent-of-origin allele specific expression as a test for Haig's kinship theory of genomic imprinting. I predict higher matrigenic expression bias in both reproductive and sterile workers under queen-less conditions. I also predict that genes showing parent-of-origin expression will be enriched for reproductive related processes.

Reproductive and sterile workers were chosen in order to provide a robust test for the kinship theory. Imprinted genes should maintain their expression bias regardless of the current reproductive state of the individual, i.e. higher matrigenic expression compared to patrigenic expression should be present in queen-less workers regardless of whether they have become reproductive or remained sterile. Additionally the use of sterile and reproductive workers allows us to assess differential expression between castes. This means I can investigate if there is a relationship between differentially expressed genes between reproductive castes and genes showing parent-of-origin expression. A high overlap of differentially expressed genes between reproductive castes with genes showing parent-of-origin expression would suggest a role for imprinted genes in reproductive caste determination.

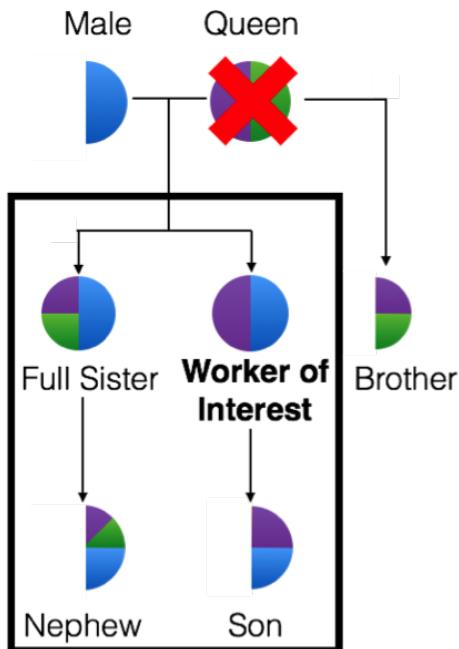

Figure 4.1: Schematic adapted from Drewell *et al.* (2012) showing the inheritance probabilities of the maternal and paternal genome in *Bombus terrestris* under queen-less conditions. Matrigenes should experience higher selection pressures for worker reproduction compared to nursing behaviour for nephews.

4.3 Methods

4.3.1 Sample collection

Reciprocal crosses of *B. terrestris dalmatinus* (native to southern Europe) and *B. terrestris audax* (native to the UK) were carried out by Biobest, Leuven. Reciprocal crosses allow subspecies-of-origin effects (i.e. the effect of genotype) to be disentangled from parent-of-origin effects (Kocher *et al.*, 2015; Galbraith *et al.*, 2016b). In order to obtain enough successful colonies multiple males and females for each cross (Fig. 4.2) were released into cages to mate. Once mating had occurred the male and female were removed. The male was immediately frozen at -80°C and female was placed in cold conditions for eight weeks to induce diapause. Ten matings were carried out for each cross.

Four successful colonies (one of each cross direction) from two ‘families’ (Fig. 4.2) were

housed at the University of Leuven and kept in 21°C with red light conditions, they were fed *ad libitum* with pollen and a sugar syrup. Callow workers were labelled with numbered disks in order to determine age and allow behaviour to be recorded. Once each colony contained approximately 30 workers the queen was removed. The colonies were then filmed under queen-less conditions for 30mins per day for 14 days in order to score individual behaviour. The following behaviours were used to classify workers: incubating, feeding larvae, inspecting brood cells, building egg cups, ventilation, biting, pushing, egg-laying, egg-eating, foraging, feeding and grooming. Workers were classified based on the frequency of each of the above behaviours as either: sterile foragers, sterile nurses, dominant reproductives or subordinate reproductives (supplementary 4.0.0).

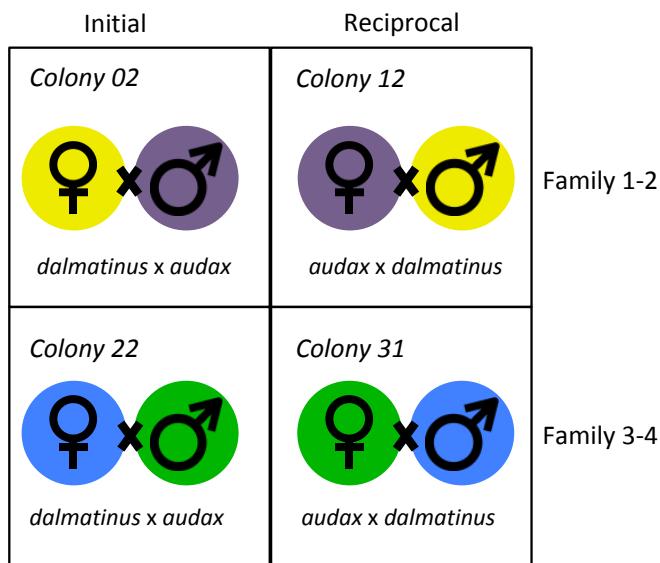

Figure 4.2: Graphic display of the family-wise reciprocal crosses carried out between *Bombus terrestris audax* and *Bombus terrestris dalmatinus*. Each colour refers to related individuals, i.e. the queen from colony 02 is the sister of the male used in colony 12. This design reduces genetic variability between the initial and reciprocal crosses.

Worker reproductive status was confirmed by ovary dissection, ovaries were scored on a 0-4 scale as in Duchateau and Velthuis (1988), entire bodies were then stored at -80°C along with the original queen mothers and male fathers. Workers were selected for sequencing based on their behavioural classification and ovary status. Two of each behavioural type per colony were selected (i.e. two dominant reproductives, two subordinate reproductives, two nurses and two foragers), with the exception of colony 22

(Fig. 4.2) which contained three subordinate reproductives and one dominant reproductive. All sterile and reproductive samples were age matched. This gave a total of 32 samples, eight per colony with four of each reproductive status, reproductive or sterile. See supplementary 4.0.0 for behavioural and ovary scoring per sample.

4.3.2 DNA and RNA extraction and sequencing

DNA was extracted from the mother and father of each colony using the Qiagen DNeasy® Blood & Tissue Kit. Thirty-two workers were selected for RNA sequencing, as described above. The head and abdomen were dissected and RNA extracted separately for each, using the Qiagen RNeasy® Lipid Tissue Kit, giving 64 total RNA samples. The quality of the DNA and RNA extraction were measured by Nanodrop and Qubit® fluorometer. Whole genome parental DNA was sequenced using 91bp paired-end reads and worker RNA was sequenced using 90bp paired-end reads on an Illumina HiSeq 2000 by BGI, China. Lane effects were minimised for the RNA samples by spreading colony and tissue samples across five lanes.

4.3.3 Generation of alternative reference genomes

Whole genome sequencing data was checked using fastqc v.0.11.05 (Andrews, 2010) and adapters and low quality reads were trimmed using Cutadapt v.1.11 (Martin, 2011). Reads were aligned to the bumblebee reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1 (Sadd *et al.*, 2015)) using BWA-mem v.0.7.15 (Li and Durbin, 2009) with standard parameters. SNPs were then called using freebayes v.1.1.0 (Garrison and Marth, 2012) which can account for the difference in ploidy between males and females, a minimum of five reads per SNP were required. Queen SNPs were then filtered so only the homozygous alternative SNPs remained. The subtractbed command from BEDtools v.2.25.0 (Quinlan and Hall, 2010) was then used to create files containing SNPs unique to either the mother/father of each colony. The individual parental SNP files were then used to create alternate reference genomes for each parent using the ‘fasta alternate reference maker’ command in GATK v.3.6 (McKenna *et al.*, 2010) (Fig. 4.3).

4.3.4 Identification of parent-of-origin expression

RNA-Seq data was quality checked and trimmed as above. STAR v.2.5.2b (Dobin *et al.*, 2016) was used to align worker RNA-seq reads to each of that colony's specific parental genomes with zero mismatches allowed. This ensures any reads containing a SNP will only be matched to the parent that the given allele was inherited from. Alignment files were then filtered using BEDtools v.2.25.0 (Quinlan and Hall, 2010) so only alignments which contain an informative SNP (a unique SNP from either the mother or father) were kept. Reads were counted for the maternal/paternal alignments, also using BEDtools v.2.25.0 (Quinlan and Hall, 2010) and SNP positions were annotated with a gene ID taken from the Bter_1.0 annotation file (Refseq accession no. GCF_000214255.1) using a custom R script (Fig. 4.3). SNPs which had zero maternal reads in at least one sample were removed completely from the analysis to avoid possible inflation of paternal counts. This would occur if the queen position was mis-called as homozygous with the missing allele matching that of the male (Galbraith *et al.*, 2016b).

Genes showing parent-of-origin expression were determined using a logistic regression model in R v.3.4.0 (<https://cran.r-project.org>). Only genes occurring in both cross directions and in both family combinations, with a minimum of two SNPs per gene were analysed, this left a total of 7,508 genes. If any gene showed zero reads for paternal counts this was changed to 1 to avoid complete separation. A quasibinomial distribution was also used to account for overdispersion within the data. Fixed factors included the direction of the cross, family and reproductive status (reproductive or sterile). Correction for multiple testing was carried out using the Benjamini–Hochberg method (Benjamini and Hochberg, 1995). Genes were determined as showing parent-of-origin expression if the allelic ratio (maternal/paternal) corrected p-value was <0.05 and the parental expression proportion was >0.6 .

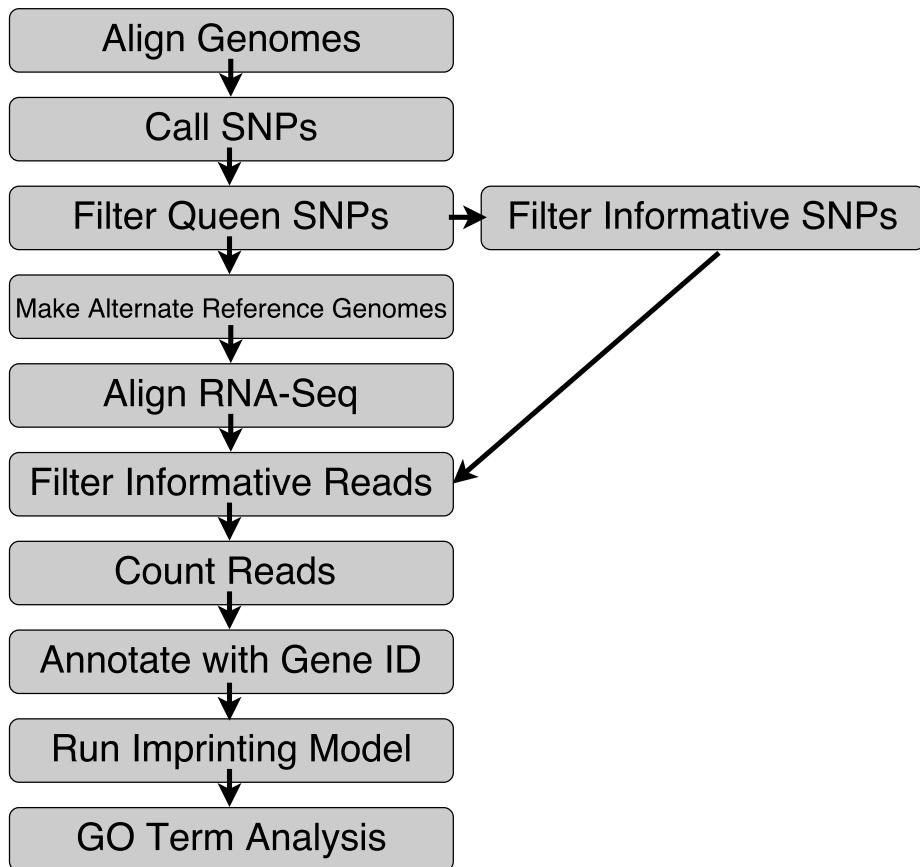

Figure 4.3: Overview of the bioinformatic pipeline used to identify genes with parent-of-origin expression. Informative SNPs refer to those unique to either the mother/father per colony.

4.3.5 Differential expression

All RNA-seq samples were aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1 (Sadd *et al.*, 2015)) using STAR v.2.5.2b (Dobin *et al.*, 2016) with standard parameters. HTseq v.0.8.0 (Anders *et al.*, 2013) was then used to count the number of reads per gene for each sample. Differential gene expression between reproductive and sterile workers for head and abdomen samples was assessed using the DESeq2 package v.1.16.1 (Love *et al.*, 2014) in R. DESeq2 allows the incorporation of a general linear model to identify differential expression: family, age, weight, direction of the cross, tissue type and reproductive status were all factors. P-values were corrected for multiple testing using the Benjamini–Hochberg method (Benjamini and Hochberg, 1995).

4.3.6 Gene ontology enrichment

GO enrichment analysis was carried out using the hypergeometric test with Benjamini-Hochberg (Benjamini and Hochberg, 1995) multiple-testing correction in a custom R script, ($q < 0.05$). This script utilised a previously made GO database for the *B. terrestris* genome, Bter_1.0 (Bebane *et al.*, 2019). GO terms for differentially expressed genes were tested for enrichment against GO terms associated with all genes identified in either the RNA-seq data from the abdomen or head. Up-regulated genes in either reproductive or sterile workers were tested for GO term enrichment against all differentially expressed genes from the respective tissue type as a background set.

Genes showing parent-of-origin expression were tested for enrichment against GO terms associated with all genes identified in both abdomen and head RNA-Seq data sets. Genes maternally or paternally biased were checked for GO term enrichment against all genes showing parent-of-origin expression as a background set. REVIGO (Supek *et al.*, 2011) was used to obtain the GO descriptions from the GO identification numbers.

4.3.7 Comparative analyses

A hypergeometric test was applied to gene lists from the differential expression analysis and the parent-of-origin expression analysis to identify potential enrichment. *B. terrestris* and *A. mellifera* homologous genes were determined as in Chapter 2 and a custom R script was then used to check for overlap between genes identified as showing parent-of-origin expression here and homologous *A. mellifera* genes identified as showing parent-of-origin expression in Galbraith *et al.* (2016b).

All code from this project is available at:

<https://doi.org/10.5281/zenodo.3235637>.

4.4 Results

4.4.1 Generation of alternate genomes

A maximum of 10 bases were trimmed from the 3' end of each read due to base bias generated by the Illumina protocol (Krueger *et al.*, 2011). The mean mapping percentage of uniquely mapped reads was $98.0\% \pm 0.3\%$ (mean \pm standard deviation). The mean number of uniquely mapped reads was $39,467,171 \pm 2,957,976$. This gave a mean genome coverage of 14.3 ± 1.1 , supplementary 4.0.1.

An average of 967,505 SNPs were called in the male samples and 1,059,559 in the queen samples (Figure 4.4). The total queen SNPs reduced to an average of 441,876 after quality filtering and filtering for homozygous alternative SNPs. There were significantly more unique SNPs found in the male of each colony compared to unique SNPs belonging to the queen of each colony, an average of 675,198 and 150,793 respectively (t-test: $t = 12.496$, $df = 5.5772$, $p < 0.000$).

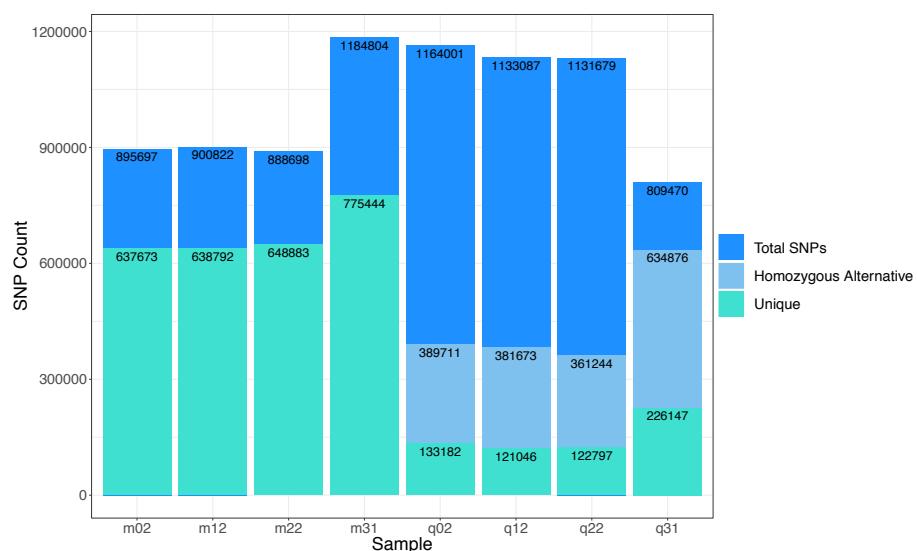

Figure 4.4: Component bar plot showing the total number of SNPs called per sample ('m' representing male and 'q' representing queen), the total number of homozygous alternative SNPs for the queens and the total number of unique SNPs per sample when compared to the corresponding male/queen for that colony.

4.4.2 Parent-of-origin gene expression

Ten bases were trimmed from the 3' end of each worker RNA-seq read due to base bias generated by the Illumina protocol (Krueger *et al.*, 2011). The mean number of uniquely mapped reads to the maternal genomes was $91.31\% \pm 0.57\%$ (mean \pm standard deviation) for the head samples and $91.53\% \pm 1.86\%$ for the abdomen samples. This equated to a mean of $13,602,926 \pm 2,774,040$ and $14,181,003 \pm 1,303,486$ uniquely mapped reads respectively (supplementary 4.0.1). The mean number of uniquely mapped reads to the paternal genomes was $91.50\% \pm 0.68\%$ (mean \pm standard deviation) for the head samples and $91.70\% \pm 1.83\%$ for the abdomen samples. This equated to a mean of $13,630,611 \pm 2,776,779$ and $14,208,273 \pm 1,307,054$ uniquely mapped reads respectively (supplementary 4.0.1).

A total of 10,211 genes had a minimum of two SNPs with at least a coverage of five reads each. Of those, 7,508 genes occurred in every cross, worker-type and tissue type. 700 genes had significant maternal/paternal expression bias in both cross-directions for queen-right workers ($q < 0.05$), and 747 were significant for queen-less workers. The expression bias was averaged across: tissue type, worker type, family and direction of cross to obtain an extremely conservative expression proportion. The significant genes were then filtered to also have an average maternal expression proportion of > 0.6 or < 0.4 to give a final confident list of genes showing parent-of-origin expression.

Reproductive workers have 163 genes showing significant parent-of-origin expression ($q < 0.05$ and maternal expression proportion > 0.6 or < 0.4 , Fig. 4.5) (supplementary 4.0.2). Sterile workers have 170 genes showing significant parent-of-origin expression ($q < 0.05$ and maternal expression proportion > 0.6 or < 0.4 , Fig. 4.5) (supplementary 4.0.3). There is no difference in the number of genes showing paternal expression bias compared to maternal expression bias in reproductive and sterile workers, assessed independently (chi-squared goodness of fit, queen-right: $X^2 = 1.3804$, $df = 1$, $p\text{-value} = 0.24$, queen-less: $X^2 = 1.5059$, $df = 1$, $p\text{-value} = 0.219$). There is no significant difference between the number of genes showing maternal expression bias compared to paternal expression bias based on reproductive status (chi-squared test of independence, $X^2 = 0$, $df = 1$, $p\text{-value} = 1$). The most extreme expression

bias is seen in the maternally expressed alleles in both reproductive castes, with 17 genes showing a maternal expression proportion of >0.9 in both reproductive and sterile workers (Fig. 4.5). There were no genes showing >0.9 paternal expression bias. Additionally we did not find any genes with sub-species expression bias.

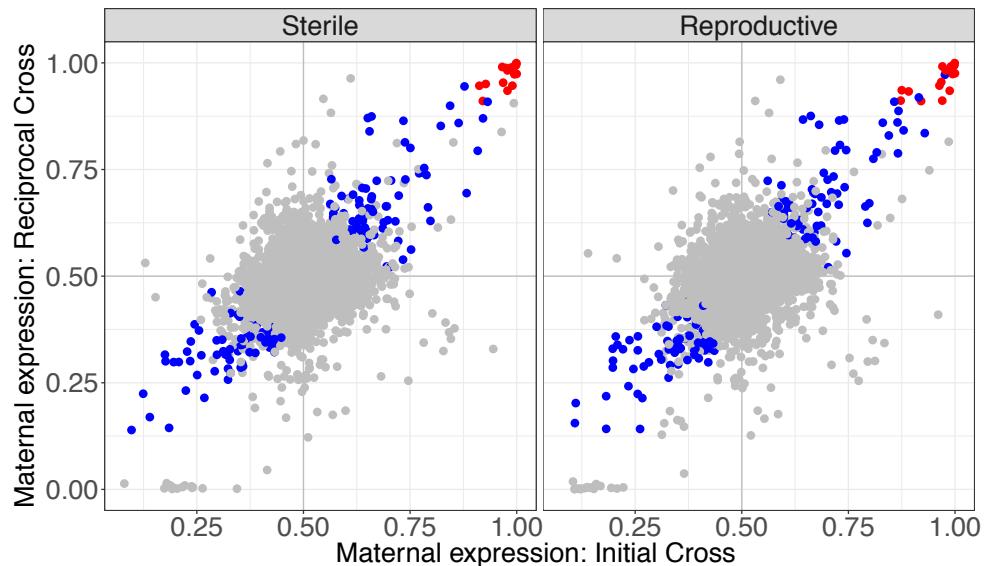

Figure 4.5: Maternal expression proportion by reproductive caste. Each point represents a gene ($N = 7,508$). Blue points are genes with significant parental expression bias ($q < 0.05$ and expression proportion >0.6). Red points are genes with significant parental expression bias ($q < 0.05$) with the proportion of expression >0.9 . The top left quadrant of each plot represents genes with a *B. terrestris audax* expression bias, the bottom right quadrant represents genes with a *B. terrestris dalmatinus* expression bias. The top right represents genes with a maternal expression bias and the bottom left represents genes with a paternal expression bias.

Reproductive and sterile workers share a significant number of genes showing parent-of-origin expression with the same parental bias (Fig. 4.6, maternal expression bias: hypergeometric test, $p < 0.000$, paternal expression bias: hypergeometric test, $p < 0.000$). There were no genes with maternal/paternal bias in one caste which had the opposite bias in the other caste.

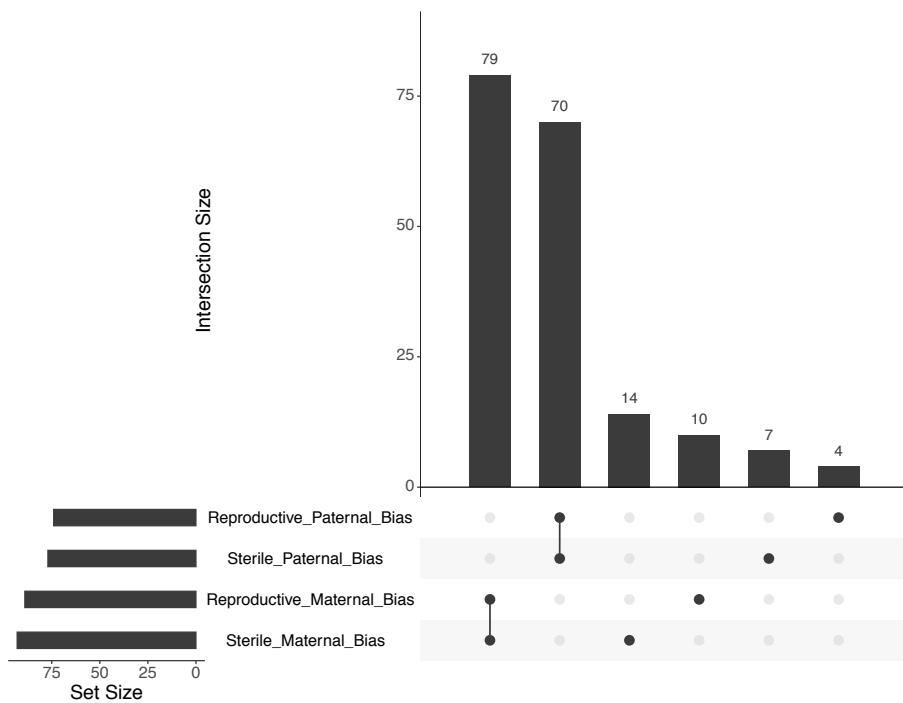

Figure 4.6: Overlapping genes showing parent-of-origin expression in reproductive and sterile workers. The set size indicates the number of genes in each list. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list.

Overall genes showing parent-of-origin expression have enriched GO terms for multiple biological processes (supplementary 4.0.4), specifically the GO terms *negative regulation of reproductive processes* (GO:2000242) and *female germ-line sex determination* (GO:0019099) are enriched. Genes with maternal and paternal bias in both reproductive and sterile workers also have enriched GO terms for multiple biological processes (supplementary 4.0.5). Specifically, paternally expressed genes in both reproductive and sterile workers are enriched for the GO term *behaviour* (GO:0007610).

Enriched GO terms for genes showing parent-of-origin expression in only reproductive or sterile workers were also enriched for various biological processes (supplementary 4.0.6). Including *histone ubiquitination* (GO:0016574) and *histone H2A monoubiquitination* (GO:0035518) in reproductive paternally expressed genes.

4.4.3 Differential expression between reproductive castes

Ten bases were trimmed from the 3' end of each read due to base bias generated by the Illumina protocol (Krueger *et al.*, 2011). The mean number of uniquely mapped reads was $95.29\% \pm 0.36\%$ (mean \pm standard deviation) for the head samples and $94.88\% \pm 1.77\%$ for the abdomen samples, when samples were mapped to the reference genome Bter_1.0. This equated to a mean of $14,196,707 \pm 2,886,920$ and $14,701,980 \pm 1,358,895$ uniquely mapped reads respectively (supplementary 4.0.7).

Tissue type explains the majority of variation within all of the RNA-seq samples, followed by reproductive status, either reproductive or sterile (Fig. 4.7). Following differential expression analysis a total of 3,505 genes were up-regulated in the abdomen of reproductive workers compared to sterile workers and 4,069 genes were down-regulated ($q < 0.01$) (supplementary 4.0.8).

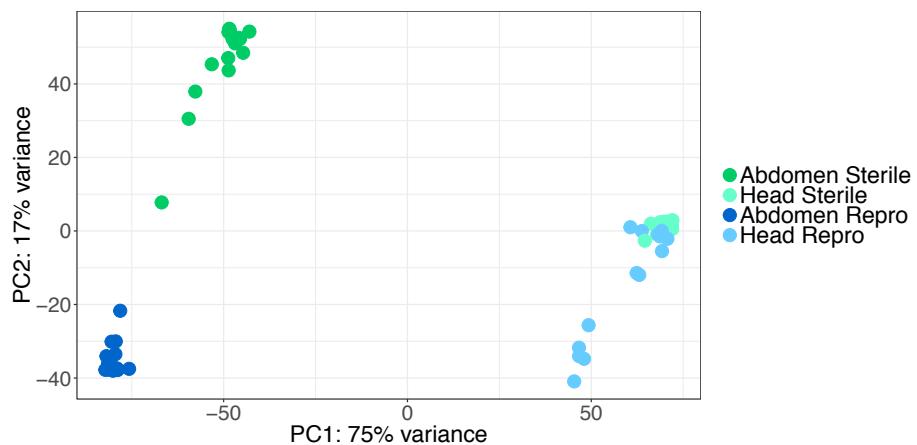

Figure 4.7: PCA plot for the expression levels of all genes ($N = 11,087$). PCA1 separates samples by tissue type and PCA2 separates samples by reproductive caste.

The enriched GO terms for the differentially expressed genes between reproductive and sterile castes in the abdomen included mostly regulatory processes but also *reproduction*

(GO:0000003) (supplementary 4.0.9). Enriched GO terms associated specifically with up-regulated genes in reproductive workers in the abdomen also included: *reproduction* (GO:0000003) and *DNA methylation* (GO:0006306) (supplementary 4.1.0), these terms were not found in the enriched GO terms for genes up-regulated in sterile workers.

Considerably fewer genes were differentially expressed in the head samples; 86 up-regulated genes in reproductive compared to sterile workers and 41 down-regulated genes ($q < 0.01$) (supplementary 4.1.1). The majority of the GO terms associated with these differentially expressed genes involved biosynthetic processes (supplementary 4.1.2). Up-regulated genes in the head tissue of reproductive workers also included *reproduction* (GO:0000003) whereas the up-regulated genes in the head tissue of sterile workers consisted of mostly metabolic processes (supplementary 4.1.2).

A heatmap of the top 100 differentially expressed genes in the abdomen clearly shows a segregation of reproductive and sterile workers (Figure 4.8a). However, the same heatmap for the head samples shows that reproductive workers form two clusters, one more closely related to sterile workers than the other. One reproductive individual also clusters within the sterile samples (Figure 4.8b). Re-running the analysis taking into account dominant and subordinate reproductive status (supplementary Fig. B.1) shows five of the seven dominant reproductive samples form the over expressed group shown in Figure 4.8b.

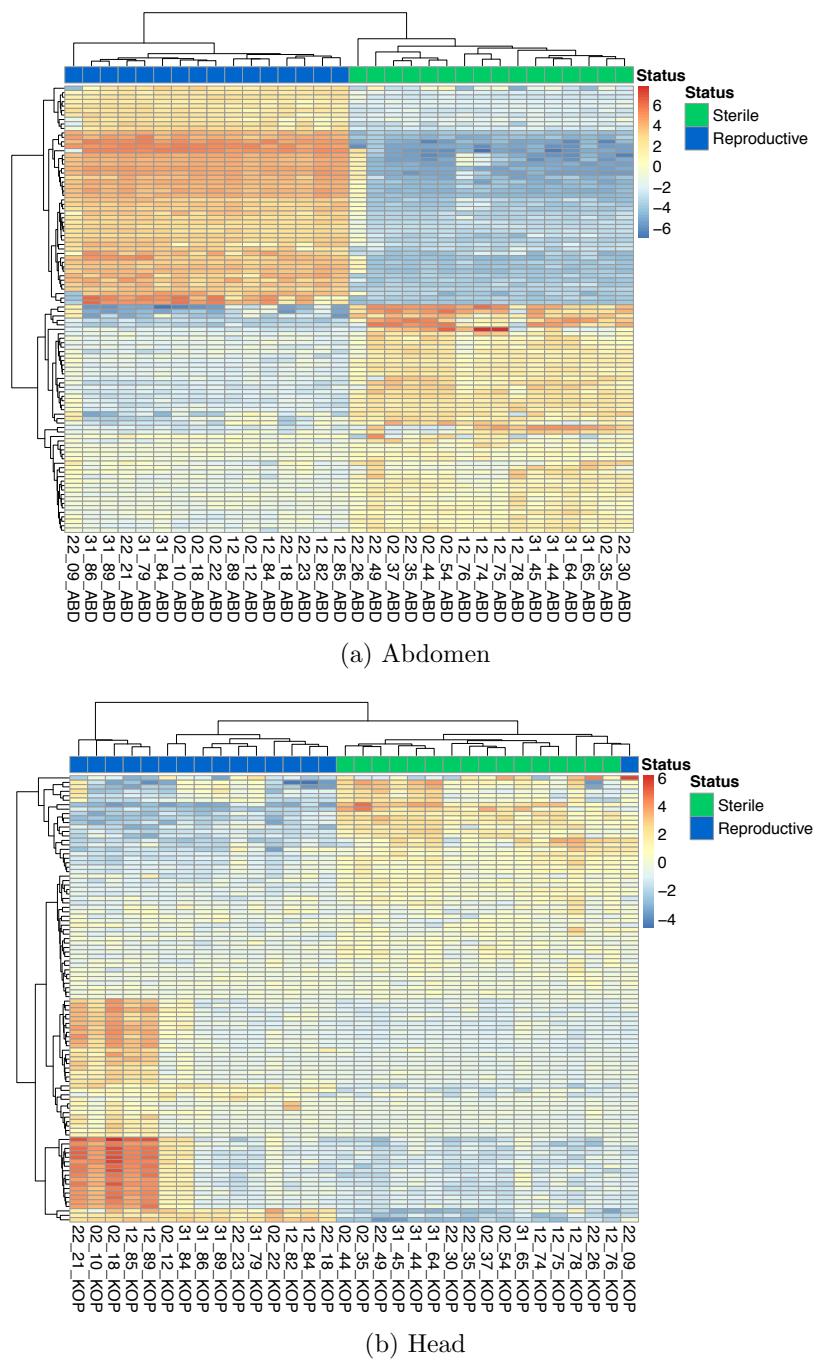

Figure 4.8: Heatmaps showing the 100 most differentially expressed genes between reproductive and sterile workers for (a) the abdomen and (b) the head. The top dendrogram shows hierarchical clustering by sample based on the counts of the genes shown. The left-hand dendrogram shows count similarity between the top 50 over expressed genes in reproductive workers and the top 50 over expressed genes in sterile workers. The red colour indicates over expression and the blue colour indicates under expression. Sample names along the bottom refer to the colony of origin, the individual and the tissue type; ABD = abdomen and KOP = head. Red indicates up-regulation and blue indicates down-regulation.

4.4.4 Overlap of parent-of-origin genes and differentially expressed genes

Genes showing maternal parent-of-origin expression are enriched for genes which are also differentially expressed in head tissue (Fig. 4.9, hypergeometric test, $p = 0.004$). Specifically *Serine Protease Inhibitor 3/4* (LOC100652301) shows maternal expression bias in both reproductive and sterile workers and is up-regulated in the head tissue of reproductive workers.

Genes with paternal parent-of-origin expression do not significantly overlap with differentially expressed genes (Fig. 4.9, hypergeometric test, $p = 0.148$). There is also no significant overlap between genes showing parent-of-origin expression bias and differential expression in the abdomen (supplementary Fig. B.2, hypergeometric test, $p = 0.996$).

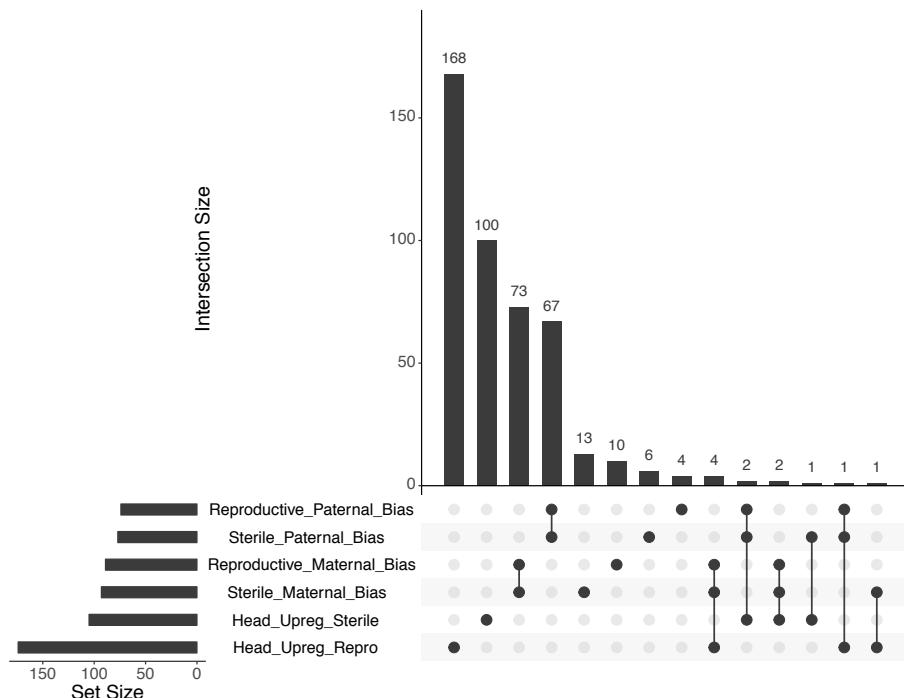

Figure 4.9: Overlapping genes showing parent-of-origin expression in reproductive and sterile workers with genes showing differential expression in head tissue. The set size indicates the number of genes in each category. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list. 7/103 genes showing maternal bias are also differentially expressed in the head.

4.4.5 Honeybee homology

A custom homology database was made between *A. mellifera* and *B. terrestris*, as in Chapter 2, containing 6,539 genes. Here 68% of differentially expressed abdominal genes were identified within the database, 43% of differentially expressed head genes and 46% of genes showing parent-of-origin expression bias (supplementary 4.1.6). Gene lists were obtained from Galbraith *et al.* (2016b), the homology database contained 38% of the differentially expressed genes identified between honeybee reproductive worker castes and 53% of the genes found to show parent-of-origin expression bias (supplementary 4.1.6).

There was no significant overlap between the genes identified as showing parent-of-origin expression between both studies (hypergeometric $p = 0.64$), with only two genes overlapping (Fig. 4.10). One of which is uncharacterised in both species (honeybee id: LOC552195, bumblebee id: LOC100648162) and the second is a serine protease inhibitor (honeybee id: LOC411889, bumblebee id: LOC100644680). The serine protease inhibitor shows paternal expression bias in honeybees and maternal bias in both bumblebee reproductive and sterile castes. It is not differentially expressed in the honeybee but it shows up-regulation in the abdomen tissue of reproductive bumblebee workers compared to sterile workers.

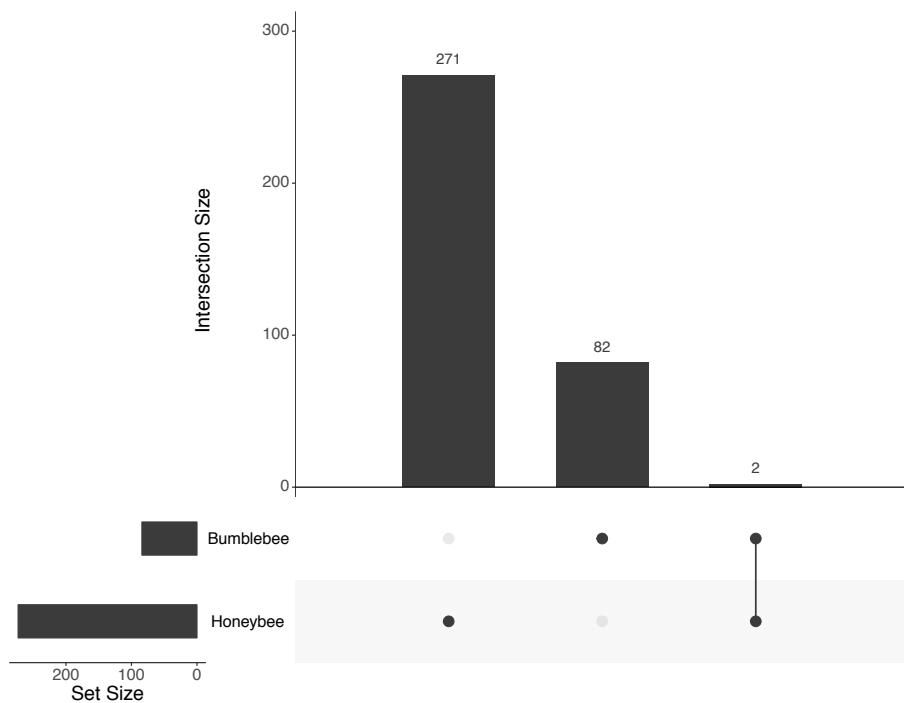

Figure 4.10: Overlapping genes showing parent-of-origin expression in reproductive and sterile workers of *B. terrestris* and *A. mellifera* (genes identified in Galbraith *et al.* (2016a)). The set size indicates the number of genes in each category. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list.

There was also no significant overlap between differentially expressed genes identified in head tissue and abdomen tissue between *B. terrestris* reproductive castes with those identified as differentially expressed between reproductive castes of *A. mellifera* from Galbraith *et al.* (2016a) (supplementary Fig. B.3, head: hypergeometric $p = 1$, abdomen hypergeometric $p = 1$).

4.5 Discussion

Using parental genome sequencing and offspring RNA-seq I have identified genes showing parent-of-origin expression in a eusocial bumblebee species. I predicted higher matrigenic expression bias in queen-less workers, in genes related to reproductive functions, following the predictions of Haig's kinship theory (Queller, 2003; Haig, 2000).

There was no difference in the number of genes showing maternal or paternal expression bias in either reproductive or sterile workers. However, genes showing the highest proportion of expression bias were all maternally expressed in both castes. Additionally, reproductive related GO terms were enriched in both maternally and paternally expressed genes along with multiple other biological processes.

These results provide some support for Haig's kinship theory; I find the most highly biased genes are maternally expressed and genes showing parent-of-origin expression are related to reproductive processes. Galbraith *et al.* (2016b) found overall patrigenic expression bias in reproductive and sterile workers from a reciprocal cross of honeybee sub-species, with significantly more patrigenic expression bias in reproductive workers compared to sterile workers, supporting Haig's kinship theory. Whilst, I do not find an overall maternal expression bias, the difference in the signal obtained between species highlights the importance of using multiple species to test various predictions when evaluating evolutionary theory.

I do not find any direct association between parent-of-origin expression and reproductive status. However, I did find different genes involved in histone modifications to be paternally expressed in reproductive workers. Histone modifications have been identified as an imprinting mark in plants (Rodrigues and Zilberman, 2015) and thought to be involved in imprinting maintenance in mammals (Delaval and Feil, 2004). Additionally histone modifications can alter gene expression by affecting gene accessibility via chromatin (Bannister and Kouzarides, 2011). Chromatin modifications have been associated with parent-of-origin expression in the fruit fly *Drosophila melanogaster* (Joanis and Lloyd, 2002). Additionally Galbraith *et al.* (2016b) also found genes involved in histone modifications showing parent-of-origin expression in the honeybee *A. mellifera*. My results hint to the possibility that parent-of-origin expression affects epigenetic mechanisms, which may in turn influence reproductive related genes. This is purely speculative and provides a potential avenue for future research to pursue.

As in Galbraith *et al.* (2016b) I also found no significant overlap of paternally expressed genes with differentially expressed genes between reproductive and sterile workers. However, I did find a significant overlap with maternally expressed genes and genes differen-

tially expressed in head tissue between reproductive and sterile castes. This significant overlap should be interpreted cautiously as only seven of the 103 unique maternally biased genes were differentially expressed in head tissue between reproductive castes. The lack of overlap of differentially expressed genes with paternally expressed genes and the small overlap with maternally expressed genes suggests parent-of-origin expression may not directly influence reproductive status in bumblebee workers.

One of the overlapping genes found to be differentially expressed in head tissue between reproductive castes which also shows maternal expression bias is a serine protease inhibitor. One of the two homologous genes identified as showing parent-of-origin expression in this study and in honeybees from Galbraith *et al.* (2016b) was also a serine protease inhibitor. Serine proteases (also known as serpins) have been shown to be involved in insect immunity in various species including: the silkworm *Bombyx mori* (Zou *et al.*, 2009), another species of silk producing moth *Antheraea pernyi* (Yu *et al.*, 2017) and the mosquito *Anopheles gambiae* (Gorman and Paskewitz, 2001). They also have functions involved with venom production in two parasitoid wasp species: *Pteromalus puparum* (Yang *et al.*, 2017) and *Nasonia vitripennis* (Qian *et al.*, 2015).

Most recently a kazal-type serine protease inhibitor has been directly linked to oocyte development in the desert locust *Schistocerca gregaria* (Guo *et al.*, 2019). A knock-down of the protein producing gene *Grelgin* by RNAi caused extreme effects on reproduction, including: diminished oocyte production and maturation, a decline in the number of eggs produced and hatching success (Guo *et al.*, 2019). Future work identifying the function of serine protease inhibitors in social insects is needed to better understand the function of parent-of-origin expression of these genes in both *B. terrestris* and *A. mellifera*.

As mentioned, only two genes were found in common between those found in Galbraith *et al.* (2016b) as showing parent-of-origin gene expression in the honeybee *A. mellifera* and those identified here in *B. terrestris*. Galbraith *et al.* (2016b) used ovaries and fat bodies as their tissues samples whereas I selected to test whole head and whole abdomen samples for strong signals of expression bias. Some imprinted genes in mammals are known to be tissue specific, such as *GBR10* which has been found to be maternally

expressed in brain and muscle tissue but not in growth plate cartilage (McCann *et al.*, 2001). Tissue specificity could account for the lack of concordance in parentally expressed genes found between *B. terrestris* and *A. mellifera*. Additionally a large proportion of genes identified in both studies were not present in the homology database created. This suggests the function of potentially imprinted genes in Hymenoptera is not strictly conserved.

The lack of conservation between genes showing parent-of-origin expression in *A. mellifera* and *B. terrestris* suggests imprinted genes have evolved rapidly in Hymenoptera. Imprinted genes in mammals show much more consistency across species, with mice and humans reportedly sharing around 50 imprinted genes out of around 150 and 100 characterised in each respectively (Babak *et al.*, 2015). Additionally, domestic cattle and pigs have been shown to share 14 imprinted genes out of 26 and 18 respectively (Tian, 2013). However, imprinted genes in plants generally show less conservation, with one study reporting 14% of maternally expressed genes and 29% of paternally expressed genes in *Capsella rubella* show the same imprinting status in *Arabidopsis thaliana*, even though both species belong to the same family, Brassicaceae (Hatorangan *et al.*, 2016). Hatorangan *et al.* (2016) suggest the lack of consistency between species could be the result of a historical shift in mating-systems. Given the differences in mating-systems between honeybees and bumblebees, and that variable predictions from the kinship theory apply to each species, rapid evolution of imprinted genes in Hymenoptera is a feasible explanation for the lack of consistency in potentially imprinted genes identified here and in Galbraith *et al.* (2016b).

Whilst I present some correlative evidence for parentally expressed genes being associated with reproduction, the GO terms associated with both maternally and paternally expressed genes are diverse. It has been suggested imprinted genes can function as a mechanism for plasticity, allowing gene regulation to change depending on environmental conditions by activating the silenced allele and increasing dosage of that gene (Radford *et al.*, 2011). Social insects display, sometimes extreme, phenotypic plasticity, where multiple discrete phenotypes (castes) can arise from a single genome within a colony. In some species this is genetically determined (Mott *et al.*, 2015). However, there is growing evidence epigenetic factors may play a role in caste determination in

some species (Lyko *et al.*, 2010; Bonasio *et al.*, 2012, Chapter 2). Matsuura *et al.* (2018) modelled a genomic imprinting mediated caste determination system in the termite *Reticulitermes speratus* and found this better explained the influence of parental phenotype on offspring than a purely genetic model. Given the diversity of genes found here showing both maternal and paternal expression bias I believe, along with Matsuura *et al.* (2018), that further experimental investigation into the role of genomic imprinting in caste determination in social insects is needed.

The identification of genes showing parent-of-origin expression in this study lays the ground work for future research to identify potential epigenetic mechanisms of allele specific expression in social insects. Genes showing allele specific expression and methylation have been previously identified in *B. terrestris* (Lonsdale *et al.*, 2017), and genes involved in the reproductive process have been shown to be differentially methylated between reproductive castes (Chapter 2). It is known methylation is the mechanism of some imprinted genes in mammals and plants (Scott and Spielman, 2006) and so investigation of parent-of-origin methylation in *B. terrestris* may be fruitful.

This is the first study to identify parent-of-origin gene expression in a eusocial bumblebee species. I found the most highly biased genes show maternal expression bias, and parentally biased genes in general in this species may be involved in worker reproduction, as predicted by Haig's kinship theory. This discovery is in line with previous work using honeybees and highlights the vital importance of using multiple species to test multiple predictions in the evaluation of evolutionary theories. Additionally, the lack of consistency between potentially imprinted genes in *B. terrestris* and *A. mellifera* suggests rapid evolution of imprinted genes in these species. Finally, the results of this study create a base for many future avenues of research including: gene function analysis of serine protease inhibitors in Hymenoptera, epigenetic mechanisms of imprinting in insects and imprinted genes as a mechanism for plasticity and caste determination.

Chapter 5

Reciprocal crosses to identify parent-of-origin methylation in the bumblebee, *Bombus terrestris*.

Hollie Marshall, Jelle Van Zweden, Annaleen Van Geystelen, Kristof Benaets, Felix Wäckers, Eamonn Mallon and Tom Wenseleers.

5.1 Abstract

Genomic imprinting is defined as parent-of-origin allele-specific expression. In order for genes to be expressed in this manner an ‘imprinting’ mark must be present to distinguish the parental alleles within the genome. In mammals and flowering plants imprinted genes are primarily associated with DNA methylation. Genes exhibiting parent-of-origin expression have recently been identified in two species of Hymenoptera; *Apis mellifera* and *Bombus terrestris*. Additionally, DNA methylation systems have been described in these species and previous work has shown a small number of genes in *B. terrestris* show allele-specific expression and allele-specific DNA methylation. However, whether DNA methylation can be transmitted in a parent-of-origin manner, making it a potential imprinting mark, is still unknown. Utilising whole genome bisulfite sequencing of parents and offspring from reciprocal crosses of two subspecies (*B. terrestris audax* and *B. terrestris dalmatinus*) I have identified parent-of-origin CpG methylation in *B. terrestris* reproductive workers. Genes containing parent-of-origin DNA methylation marks were not consistent with those previously described as showing parent-of-origin expression. This suggests DNA methylation may not be directly responsible for altering gene expression of potentially imprinted genes. It is possible an interplay of epigenomic mechanisms, acting in both *cis* and *trans*, are what drive parent-of-origin expression. Future work exploring the relationship between parent-of-origin DNA methylation and open chromatin regions will further elucidate the molecular mechanisms of imprinted genes in insects.

5.2 Introduction

Genomic imprinting is defined as parent-of-origin allele-specific expression (Rodrigues and Zilberman, 2015). In order for genes to be expressed in this manner an ‘imprinting’ mark must be present to distinguish the parental alleles within the genome. In mammals and flowering plants imprinted genes are primarily associated with DNA methylation in areas of the genome known as imprinting control regions (ICRs) (Barlow and Bartolomei, 2014). The presence of DNA methylation, as an imprinting mark, has been associated with both allelic silencing as well as allelic expression (Drewell *et al.*, 2012; Barlow, 2011).

DNA methylation can serve to repress expression of a individual allele by preventing a transcription factor from binding to a promoter region (Drewell *et al.*, 2012). It is also thought DNA methylation may signal the recruitment of histone modifications which result in heterochromatin formation, silencing the expression of all alleles within a region (Barlow, 2011). DNA methylation can also enable allele-specific expression of imprinted genes by silencing an ‘imprinting control element’, such as a long non-coding RNA, which, when expressed, would cause transcriptional silencing of nearby genes (Barlow, 2011). It is also worth noting whilst most identified imprinted genes in mammals have some association with methylation there are cases where imprinting has been observed independently of methylation and instead associated solely with a particular histone modification (Inoue *et al.*, 2017).

Whilst parent-of-origin expression and the underlying epigenetic marks are well documented in mammals and flowering plants, it is only recently that genes exhibiting parent-of-origin expression in insects have been identified (Galbraith *et al.*, 2016a, Chapter 4). Previous studies had only found sub-species specific allelic expression (Wang *et al.*, 2016), and the results of one study (Kocher *et al.*, 2015) were later found to be driven by sub-species incompatibilities (Gibson *et al.*, 2015). However, imprinted chromosomes or chromosome regions have been identified in multiple insect species, including *Drosophila melanogaster* (Anaka *et al.*, 2009), with various species exhibiting paternal genome elimination, where only the maternal chromosomes of a male are

passed on to the subsequent offspring (Hodson *et al.*, 2017). Given the lack of research into parent-of-origin gene expression in insects, little is known about the potential epigenetic mechanisms driving the imprinting of parental alleles. DNA methylation has recently been shown to exist in all orders of insects, except for Diptera (Bewick *et al.*, 2016), it is therefore possible DNA methylation may also play a role in genomic imprinting in insects, as seen in mammals and flowering plants.

Insect DNA methylation, like mammalian methylation, is generally found in a CpG context (referring to a cytosine base immediately followed by a guanine base) (Glastad *et al.*, 2014). It is found in lower levels, with <1% - 14% of CpGs being methylated, compared to mammals where around 70% of CpG sites are methylated (Bewick *et al.*, 2016; Feng *et al.*, 2010). Additionally DNA methylation in insects is generally located in gene bodies and associated with more highly expressed genes, such as housekeeping genes (Provataris *et al.*, 2018; Elango *et al.*, 2009; Foret *et al.*, 2009).

The function of DNA methylation in insects is largely unknown and thought to be variable based on the range of overall levels between classes (Provataris *et al.*, 2018). Both insect species known to show parent-of-origin gene expression belong to the order: Hymenoptera (Galbraith *et al.*, 2016b, Chapter 4). In Hymenoptera, DNA methylation has been associated with caste differentiation in various species, for example: *Apis mellifera* (Lyko *et al.*, 2010), *Bombus terrestris* (Chapter 2), *Zootermopsis nevadensis* (Glastad *et al.*, 2016) and *Camponotus floridanus* (Bonasio *et al.*, 2012). Although no association between the level of sociality of a species and the level of DNA methylation has been found (Weiner *et al.*, 2013; Glastad *et al.*, 2017). The leading theory for the evolution of genomic imprinting, Haig's kinship theory (Haig, 2000), predicts social insects should display imprinted genes. It has also been thought genomic imprinting in social insects could contribute to caste differentiation (Matsuura *et al.*, 2018).

Here, I identify parent-of-origin methylation marks in the eusocial bumblebee *Bombus terrestris*, to investigate the hypothesis that DNA methylation can also act as an epigenetic mark for genomic imprinting in social insects. *B. terrestris* is the ideal model species to explore this hypothesis; it has previously been shown to exhibit parent-of-origin gene expression of both maternally derived and paternally derived alleles (Chap-

ter 4), *B. terrestris* possess a fully functional methylation system (Liu *et al.*, 2018; Amarasinghe *et al.*, 2014, Chapter 2) and it displays allele-specific methylation at multiple loci throughout the genome (Lonsdale *et al.*, 2017, Chapter 3). This study will determine if some of these allele-specific DNA methylation events which exist in *B. terrestris* are determined in a parent-of-origin manner. Combined with previously generated parent-of-origin gene expression data (Chapter 4) this study may provide the first evidence for a molecular imprinting mechanism in Hymenoptera.

I have generated whole genome bisulfite sequencing (WGBS) libraries from the parents and pooled worker offspring of two family-wise reciprocal crosses. Male *B. terrestris* are haploid meaning every worker daughter inherits the same copy of the paternal genome, whilst queens are diploid meaning there are two possible maternal alleles that can be present in the offspring. SNPs unique to the father and homozygous SNPs unique to the queen mother have been used to identify the parental origin of alleles within the offspring genome, allowing parent-of-origin methylation to be identified. Utilising WGBS I have also identified methylation differences between queens and males and established if these methylation differences are maintained in the parental alleles of the offspring. Finally, taking advantage of the previously generated parent-of-origin allele-specific expression data set from Chapter 4 I have searched for a link between parent-of-origin methylation and parent-of-origin expression in *B. terrestris*, exploring the potential role of DNA methylation in genomic imprinting in insects.

5.3 Methods

5.3.1 Sample collection

The samples used in this chapter are from the same experiment as those used in Chapter 4. However, different colonies were selected. Ideally I would have used the same colonies for the exploration of parent-of-origin expression and methylation. However, the gene expression data were already generated before the collaboration between labs was established, see page iii.

Reciprocal crosses of *B. terrestris dalmatinus* (native to southern Europe) and *B. terrestris audax* (native to the UK) were carried out by Biobest, Leuven. Four successful colonies (one of each cross direction) from two ‘families’ (Fig. 5.1) were housed at the University of Leuven and kept in 21°C with red light conditions, they were fed *ad libitum* with pollen and a sugar syrup. Callow workers were tagged in order to determine age.

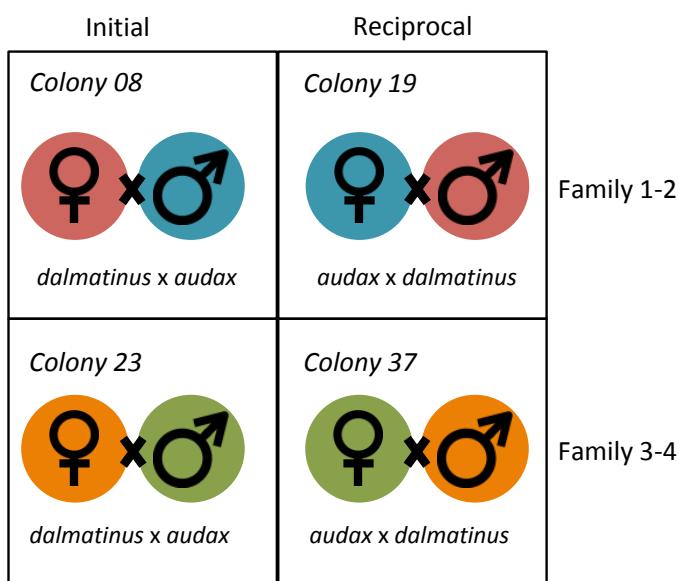

Figure 5.1: Graphic display of the family-wise reciprocal crosses carried out between *Bombus terrestris audax* and *Bombus terrestris dalmatinus*. Each colour refers to related individuals, i.e. the queen from colony 08 is the sister of the male used in colony 19. This design reduces genetic variability between the initial and reciprocal crosses.

Worker reproductive status was confirmed by ovary dissection, ovaries were scored on a 0-4 scale as in Duchateau and Velthuis (1988), entire bodies were then stored at -80°C along with the original queen mothers and male fathers. Three reproductive workers, aged 16-17 days, were selected from queen-less conditions from each of the crosses (supplementary 5.0.0).

5.3.2 DNA extraction and sequencing

DNA was extracted from whole heads of the mother and father of each colony as well as from 12 reproductive workers (three per colony) using the Qiagen DNeasy® Blood & Tissue Kit following the manufacturers protocol. Reproductive workers were chosen to reduce the variation between samples as sterile and reproductive worker castes show different methylation profiles (Chapter 2). Each sample was treated with RNase. DNA from the three reproductive samples per colony were pooled to produce one representative offspring sample per colony. DNA quantity and quality were determined by Nanodrop and Qubit® fluorometers as well as via gel electrophoresis.

DNA samples were originally sent to the Centre for Genomic Research at the University of Liverpool for whole genome bisulfite sequencing, using paired-end libraries (2 x 150bp) across two lanes of an Illumina HiSeq 4000 platform with 40% phiX inclusion. However, data received were of extremely poor quality (Appendix C). There was enough DNA to re-sequence the samples and therefore samples were sent, by the University of Liverpool, to BGI Tech Solution Co., Ltd.(Hong Kong) for sequencing using the same method. The method consists of; DNA fragmentation to 100-300bp by sonication, purification using the Qiagen MiniElute PCR Purification Kit, incubation at 20°C with an end repair mix, 3' adenine addition and ligation of methylated adapters, purification of 300-400bp fragments with Qiagen QIAquick Gel Extraction Kit, bisulfite treatment with the Zymo Methylation-Gold kit, PCR and a final size selection of 350-400bp fragments using the Qiagen QIAquick Gel Extraction Kit. A 1% lambda DNA spike was included in all libraries in order to assess bisulfite conversion efficiency, as the lambda genome is known to be unmethylated.

5.3.3 Differential methylation

Sequencing data were checked using fastqc v.0.11.5 (Andrews, 2010) and poor quality bases were trimmed using cutadapt v.1.11 (Martin, 2011). Libraries were then aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1, (Sadd *et al.*, 2015)) using Bismark v.0.16.1 (Krueger and Andrews, 2011) and bowtie2 v.2.2.6 (Lang-

mead and Salzberg, 2012) with standard parameters. Bismark was also used to extract methylation calls and carry out deduplication. Coverage outliers (above the 99.9th percentile) were removed along with bases covered by less than 10 reads. The methylation status of each CpG was then determined, using the ‘methylation status calling’ (MSC) procedure, as described in Cheng and Zhu (2014). CpG sites were then filtered to remove any site that did not return as methylated in at least one sample.

Differential methylation was assessed at the CpG level in pair-wise comparisons (queen-male, queen-worker, male-worker) using the R package *methylKit* (Akalin *et al.*, 2012). A logistic regression model was applied to each comparison. For differential methylation between workers and queens/males the model included subspecies (*B. t. audax*, *B. t. dalmatinus* or mixed; for the worker) and colony as covariates. For differential methylation between males and queens the model covariates were subspecies and family. The inclusion of colony or family as a covariate allows the relatedness between workers and parents or workers and parental siblings to be taken into account.

For a CpG to be differentially methylated a minimum difference of at least 10% methylation and a q-value of <0.05 were required. Genes were determined as differentially methylated genes if they contained at least one differentially methylated CpG and had an overall weighted methylation difference of >10%. Weighted methylation level is determined as the total number of methylated cytosines (C) within a region (*i*) divided by the total coverage of a region (Equation 5.1), as described in Schultz *et al.* (2012).

$$\sum_{i=1}^n C_i / \sum_{i=1}^n C_i + T_i \quad (5.1)$$

5.3.4 Generation of alternative reference genomes

Data were aligned and deduplicated as in section 5.3.3. SNPs were then called from the parental bisulfite-genomes using a high-stringency SNP caller designed for bisulfite treated data, Bis-SNP v.1.0.0 (Liu *et al.*, 2012). In order to use Bis-SNP, the alignment output files (.bam) were sorted and indexed using samtools v.1.3.2 (Li *et al.*, 2009) and

read group data was added using picard v.2.6.0 (Broad Institute, 2018).

After quality filtering, queen SNPs were then filtered so only the homozygous alternative SNPs remained. Males SNPs were also filtered to remove any potentially mis-labelled heterozygous SNPs, this can occur as Bis-SNP cannot take ploidy into account. The *subtractbed* command from BEDtools v.2.25.0 (Quinlan and Hall, 2010) was then used to create files containing SNPs unique to either the mother/father of each colony. The individual parental SNP files were then used to create alternate reference genomes (Fig. 5.2) for each parent using the *fasta alternate reference maker* command in GATK v.3.6 (McKenna *et al.*, 2010).

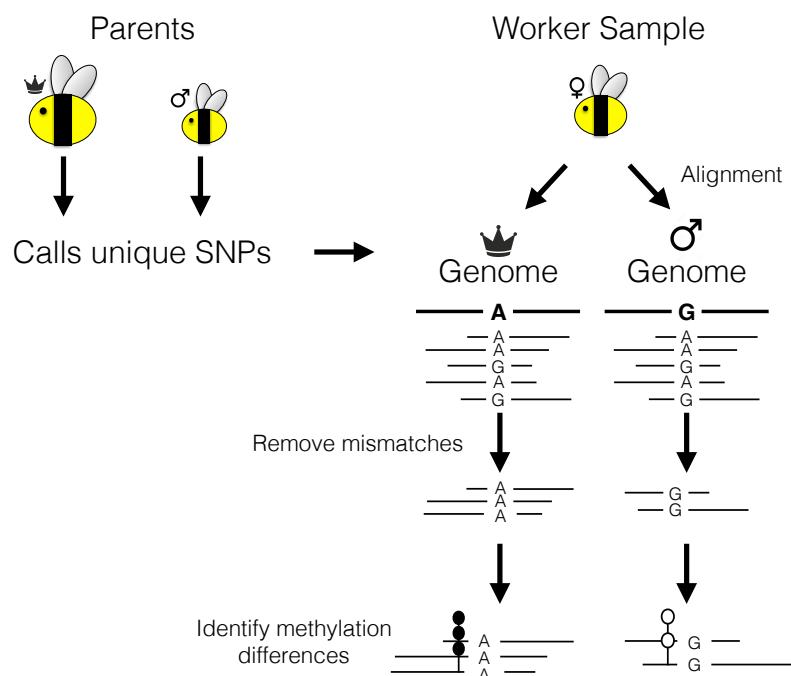

Figure 5.2: Overview schematic for identifying allelic methylation differences in the worker offspring. SNPs unique to either the mother or father are used to create phased reference genomes. The worker daughter sample is then aligned to both genomes and reads are filtered to keep only those with no bisulfite related mismatches. Methylation differences between the alleles can then be assessed and compared to the parental methylation levels of that gene.

5.3.5 Identification of parent-of-origin methylation

WGBS libraries of the pooled workers were aligned to their parent-specific phased genomes using Bismark v0.18.1 (Krueger and Andrews, 2011). The *-non_bs_mm* option

was implemented during alignment which reports the number of non-bisulfite related mismatches per read. Alignment files were then filtered to keep only reads with zero non-bisulfite related mismatches. This makes sure only reads matching the unique parental allele are kept per alignment (Fig. 5.2), giving a set of reads unique to each parental allele. Alignment files were then deduplicated using Bismark v0.18.1 (Krueger and Andrews, 2011), and sorted using samtools v.1.3.2 (Li *et al.*, 2009).

CpG sites per allelic read set were then filtered on a minimum coverage of 10 and coverage outliers (above 99.9th percentile) were removed, additionally only CpGs found in all allelic read sets were kept. The methylation status of each CpG was then determined, using the ‘methylation status calling’ (MSC) procedure, described in Cheng and Zhu (2014). CpG sites were then filtered to remove any site that did not return as methylated in at least one allelic read set.

A differential methylation analysis was then carried out between the allelic read sets (maternal alleles vs paternal alleles) using a logistic regression model implemented by methylKit (Akalin *et al.*, 2012) with Benjamini-Hochberg correction for multiple testing (Benjamini and Hochberg, 1995). CpGs were classed as showing parent-of-origin methylation if there was a minimum of 5% methylation difference between the allelic read sets and a q-value <0.05.

The general linear model (*glm*) applied in Chapter 4 to identify genes showing parent-of-origin expression is not appropriate for identifying parent-of-origin methylation. Expression data per SNP is count based and so a proportion of maternal/paternal expression can be generated per SNP per gene and the *glm* designed can be applied. However, methylation data is already proportional in nature, i.e. a single methylation site consists of the proportion of methylation reads and unmethylated reads and so these data cannot be modelled using this previous approach.

To identify the relationship between the methylation level of the alleles in the offspring and the methylation level of the genes in the parents the mean weighted methylation level of each gene was calculated using Equation. 5.1. The weighted methylation level per gene/allele was calculated for the workers, queens and males and then a mean was taken across each set. This gave a methylation level for each gene for queens /

males / maternal worker alleles and paternal worker alleles. The methylation difference between worker alleles was calculated as the paternal allelic methylation level minus the maternal allelic methylation level. The difference in methylation level between genes in queens and males was calculated as the male gene methylation level minus the queen gene methylation level. The parental methylation difference was then plotted against the worker allelic difference to identify genes which show high methylation in the parents and in the inherited parental allele, determining whether methylation level of a gene in the parent is maintained in the parental allele of the offspring.

5.3.6 Gene ontology enrichment

Gene ontology (GO) terms for *B. terrestris* were taken from a custom database made in Bebane *et al.* (2019). GO enrichment analysis was carried out using the hypergeometric test with Benjamini-Hochberg (Benjamini and Hochberg, 1995) multiple-testing correction, $q < 0.05$. GO terms from differentially methylated genes between queens and males and GO terms for genes identified as containing a differentially methylated CpG between alleles in workers were tested against a GO term database made from the GO terms associated with all methylated genes. Genes were determined as methylated if they had a mean weighted methylation level greater than the bisulfite conversion error rate of > 0.05 in either queens, males or workers. REVIGO (Supek *et al.*, 2011) was used to generate GO descriptions from the GO ids.

5.3.7 Comparative analyses

Genes identified as showing parent-of-origin expression from Chapter 4 and genes which are differentially methylated between worker reproductive castes from Chapter 2 were checked for overlap with genes found here to contain a parent-of-origin methylated CpG using a hypergeometric test.

To identify trends between parent-of-origin expression and parent-of-origin methylation the allelic weighted methylation difference was determined as the male allelic methylation level - the queen allelic methylation level. The paternal expression proportion

was then plotted for each gene that shows some methylation difference between worker alleles.

All bioinformatic scripts used within this chapter can be found at: <https://doi.org/10.5281/zenodo.3235646>.

5.4 Results

5.4.1 DNA extraction and data quality

DNA extracted from whole head tissue of all queens, males and reproductive workers gave suitable quantities for sequencing (supplementary 5.0.1). DNA generally showed little degradation across samples, except for three of the four male samples (Fig. 5.3).

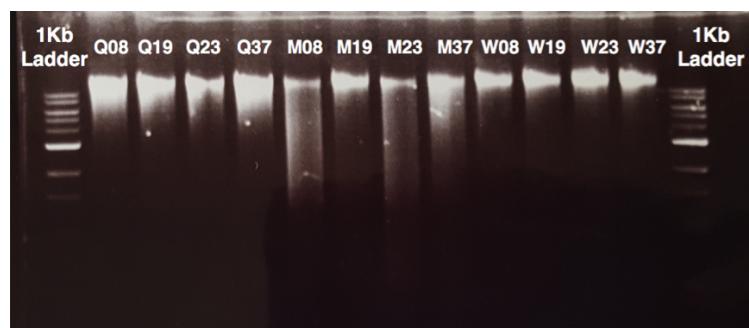

Figure 5.3: 2% agarose gel of DNA extracted from head tissue with 1Kb ladders in lanes 1 and 14. ‘Q’ refers to the queen samples, ‘M’ refers to the male samples and ‘W’ refers to the pooled worker samples, the corresponding numbers refer to the colony of origin. Some degradation can be seen in the samples: M08, M23 and M37.

An average of $60.1\% \pm 3.0\%$ (mean \pm standard deviation) of the data received from BGI aligned uniquely to the reference genome, after removal of PCR duplicates the final genome coverage was $13.9X \pm 1.6X$ (supplementary 5.0.2). The bisulfite conversion efficiency, determined by the lambda spike, was 99.5%. After correcting methylation levels for an error rate of 0.05% methylation was only detected in a CpG context with an average single-site level of $0.25\% \pm 0.05\%$ (supplementary 5.0.3).

5.4.2 Differential methylation

Bumblebee workers, queens and males show different CpG methylation profiles, with males clustering away from the two female castes (Fig. 5.4a and 5.4b). The levels of weighted methylation across all methylated genes differ significantly between sample type (Kruskal-Wallis test, chi-squared = 10011, df = 3, p <0.000, (Fig. 5.4c). The average weighted methylation per gene in males is 0.129 ± 0.222 (mean \pm standard deviation), in queens is 0.139 ± 0.221 and in reproductive workers is 0.213 ± 0.267 . Reproductive workers have significantly higher levels of CpG methylation per gene compared to males and queens (Dunn test with Benjamini-Hochberg correction, compared to males: Z = -10.33, q <0.000, compared to queens: Z = -5.36, q <0.000). Queens also have higher CpG methylation per gene compared to males (Dunn test with Benjamini-Hochberg correction, Z = -4.35, q <0.000).

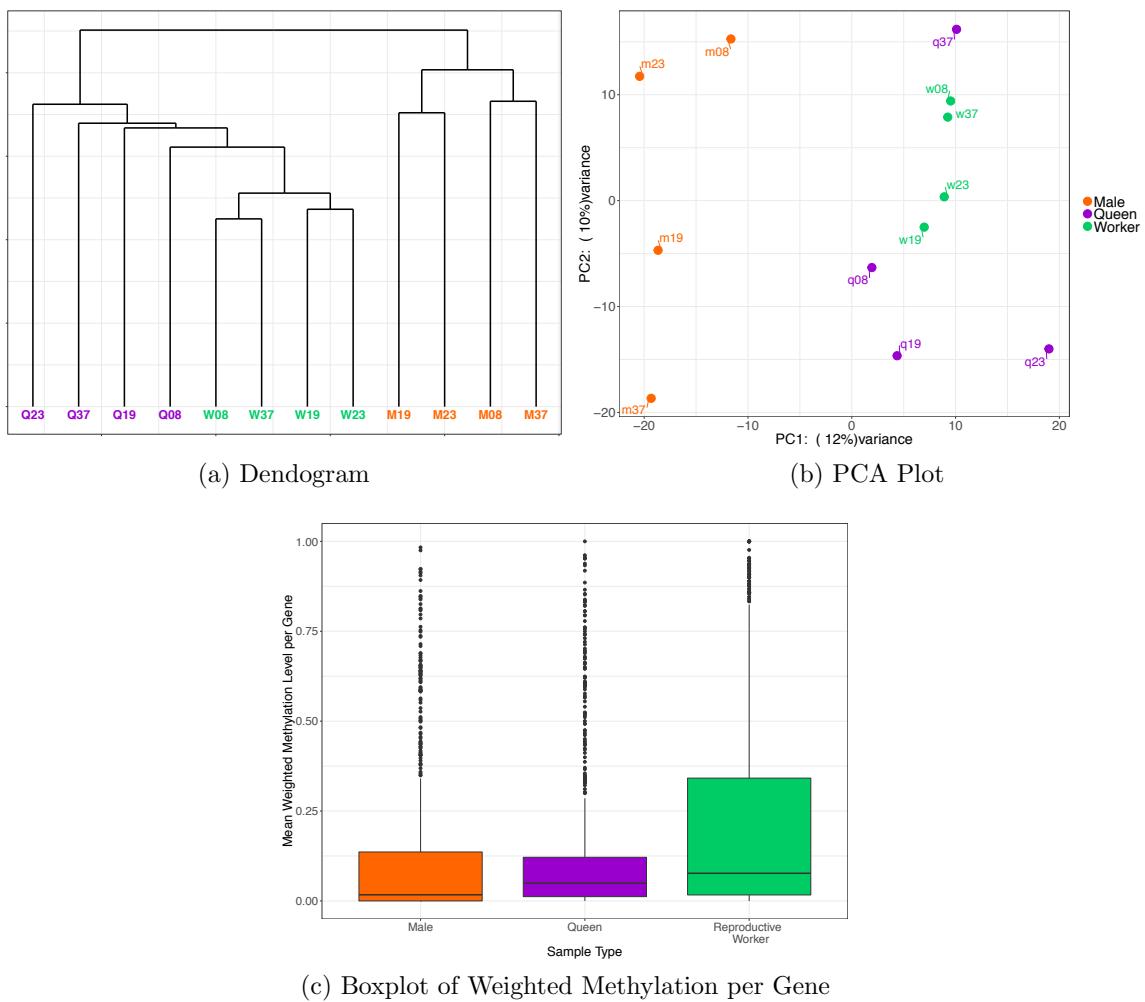

Figure 5.4: (a) Hierarchical cluster based on methylation correlation distances calculated using the ‘ward’ method, showing samples cluster by gender (total CpGs = 28,735,33). (b) PCA plot showing samples cluster primarily by gender but with much more spread in the queens and males (total CpGs = 28,735,33). (c) Boxplots showing the varying weighted methylation levels across genes which have >0 weighted methylation in all three castes, N = 2,663. Each boxplot shows the median along with the 25th and 75th percentile. The whiskers represent 1.5X the interquartile range. Outliers are represented as additional black points.

There were no differentially methylated CpG sites found between workers and males and between workers and queens. A total of 703 CpGs were differentially methylated between queens and males, of these 660 were found to be contained within a gene, with 412 unique genes showing differential methylation (supplementary 5.0.4). Of these 344 genes also had a weighted methylation difference of at least 10% between queens and males and were classed as differentially methylated genes (supplementary 5.0.5).

There were significantly more genes hypermethylated (i.e. with higher methylation) in queens compared to males (chi-squared goodness of fit; $\chi^2 = 5.1279$, $df = 1$, $p = 0.023$). With queens showing 193 hypermethylated genes and males showing 151 hypermethylated genes.

Enriched GO terms for the differentially methylated genes included a variety of biological processes (supplementary 5.0.5), specifically ‘*spermatogenesis*’ (GO:0007283), ‘*dosage compensation by inactivation of X chromosome*’ (GO:0009048) and ‘*chromosome organisation*’ (GO:0051276) were enriched.

Enriched GO terms specifically associated with hypermethylated genes in males included mostly developmental processes (supplementary 5.0.7). Enriched GO terms specifically associated with hypermethylated genes in queens included mostly biosynthetic processes (supplementary 5.0.7).

5.4.3 Parent-of-origin methylation

SNPs were called from the parental methylation data, an average of $21,688 \pm 9,143$ (mean \pm standard deviation) unique homozygous alternative SNPs were identified in the queen which were not present in the corresponding male sample and an average of $42,152 \pm 4,000$ unique SNPs were identified in the male sample which were not present in the corresponding queen sample (Fig. 5.5).

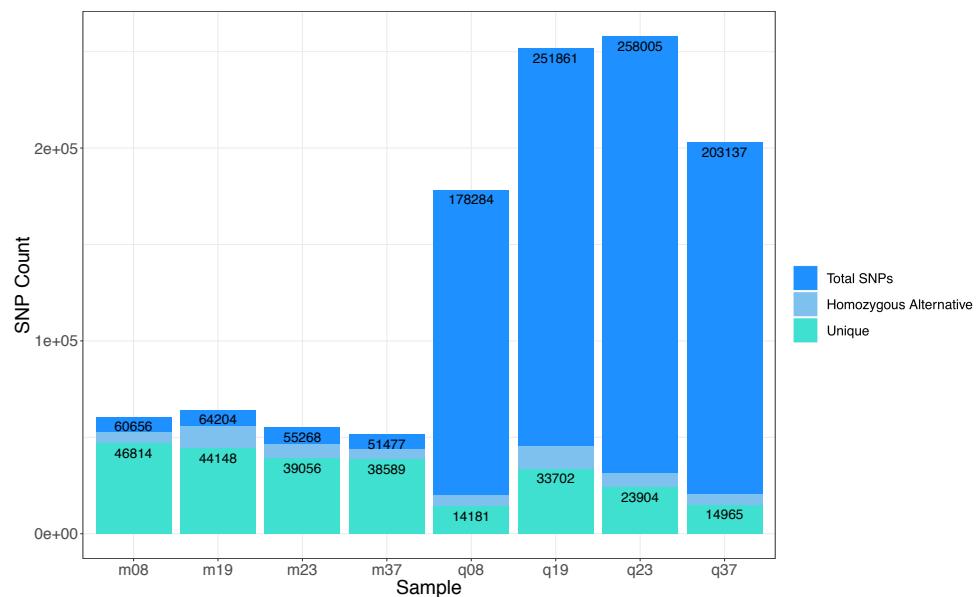

Figure 5.5: Component bar chart showing the total number of SNPs called per sample after quality filtering and, of those, the number which are unique per sample.

Alignment rates of the worker samples to their parentally phased genomes were slightly higher than to the standard reference genome, with similar alignment rates found between the father's ($62.1\% \pm 1.9\%$) and mother's ($62.0\% \pm 1.9\%$) phased genome. This increased coverage to $14.1X \pm 0.4X$ (supplementary 5.0.8).

Of the allelic read sets (reads aligning to either the maternal or paternal genome) an average of $21.5\% \pm 0.6\%$ were removed as they contained a non-bisulfite mismatch, this reduced the average coverage to $11.1X \pm 0.4X$. The average number of CpGs per allelic read set with coverage >10 was $3,788,483 \pm 868,658$. However, of these, only 434,717 CpGs were identified in every allelic read set. After calling the methylation status of each CpG in each allelic read set, using the MSC procedure, and filtering so only CpGs remained that were methylated in at least one allelic read set, only 6,157 CpGs were subjected to a differential methylation test between maternal/paternal alleles to identify parent-of-origin CpG methylation.

11 CpGs showed consistent parent-of-origin allele-specific methylation across all reciprocal crosses ($q < 0.05$ and a minimum difference of 5%). Ten of these are located in genes and of those, 9 are located in exons, Table 5.1.

Table 5.1: Genes identified as showing parent-of-origin methylation. Allele refers to the hypermethylated allele.

The genes identified as containing a CpG showing parent-of-origin methylation had various enriched GO terms including: *response to ecdysone* (GO:0037076) and *ecdysone receptor-mediated signaling pathway* (GO:0035076), supplementary 5.0.9.

The weighted methylation levels of each of the parental alleles within the worker were calculated along with the weighted methylation level of each gene within the parents. A linear model was fitted with the worker allelic methylation difference (male allele - queen allele) as the independent variable to test for the effect of parental methylation differences on allelic methylation levels in the offspring. There was no significant effect of parental methylation difference (male gene - queen gene) on worker allelic methylation difference ($F_{1, 70} = 1.618$, p-value = 0.207). No significant correlation was found between parental methylation difference and worker allelic methylation difference (Fig. 5.6), a positive correlation of one would indicate methylation in the parental genes is maintained in the parental alleles in the offspring.

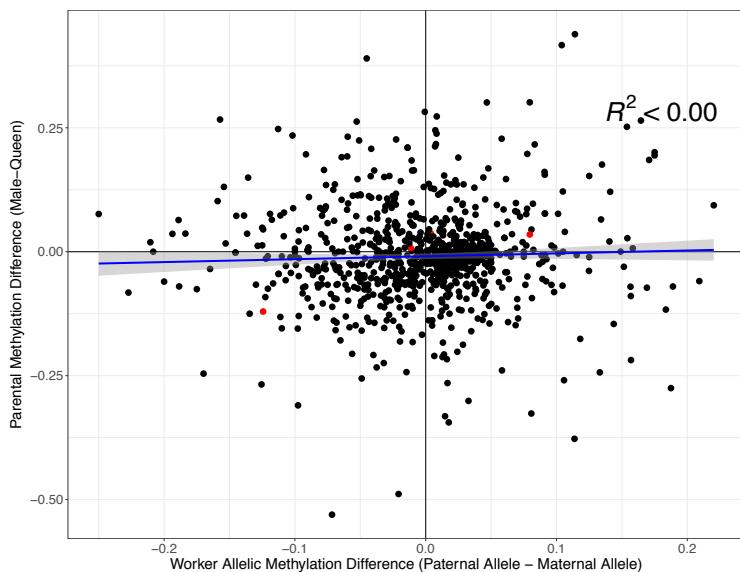

Figure 5.6: Scatter graph of genes which show a weighted methylation difference between worker alleles and the parental weighted methylation difference of each gene. Each point represents a single gene, $N = 986$. The red points show genes which also contain a significant differentially methylated CpG between alleles. The blue line shows a fitted linear regression with grey areas indicating 95% confidence intervals. Genes in the top right quadrant show higher methylation in the male inherited allele and higher methylation levels in the male gene compared to the queen gene. Genes in the bottom right quadrant show higher methylation in the male inherited allele and higher methylation levels in the queen gene compared to the male gene. Genes in the bottom left quadrant show higher methylation in the queen inherited allele and higher methylation levels in the queen gene compared to the male gene. Genes in the top left quadrant show higher methylation in the queen inherited allele and higher methylation levels in the male gene compared to the queen gene.

5.4.4 Relationship between parent-of-origin methylation and parent-of-origin expression

None of the genes containing a significant differentially methylated CpG between maternal / paternal alleles also show significant parent-of-origin expression from Chapter 4. A linear model was fitted with the worker allelic methylation difference as the independent variable to test for the effect of parent-of-origin expression. There was no significant effect of expression (paternal expression proportion) on worker allelic methylation difference ($F_{1,60} = 0.2828$, $P\text{-value} = 0.596$). No significant correlation was found between paternal expression proportion and worker allelic methylation difference (Fig.

5.7), a positive correlation of one would indicate higher paternal allelic methylation is linked to higher paternal expression.

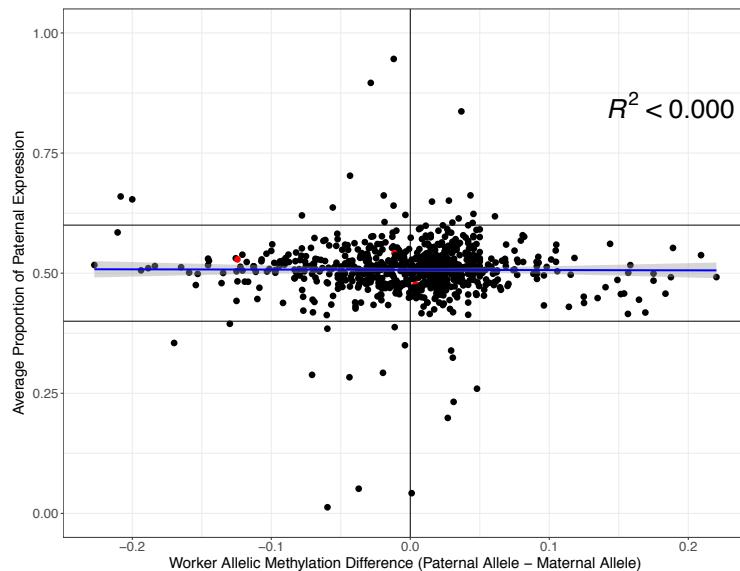

Figure 5.7: Scatter graph of genes showing a weighted methylation difference between worker alleles and the proportion of paternal expression for each gene from Chapter 4. Each point represents a single gene, $N = 805$. The red points show genes which also contain a significant differentially methylated CpG. The horizontal lines show the minimum proportion of expression required for calling a gene as showing parental-expression bias, i.e. >0.6 and <0.4 . The blue line shows a fitted linear regression with grey areas indicating 95% confidence intervals. Genes in the top right quadrant show higher methylation in the male inherited allele and higher expression of the paternally inherited allele. Genes in the bottom right quadrant show higher methylation in the male inherited allele and higher expression of the maternally inherited allele. Genes in the bottom left quadrant would show higher methylation in the queen inherited allele and higher expression of the maternally inherited allele. Genes in the top left quadrant show higher methylation in the queen inherited allele and higher expression of the paternally inherited allele.

There was no significant overlap between genes containing a differentially methylated CpG between worker alleles and genes which are also differentially methylated between worker reproductive castes from Chapter 2 (hypergeometric test, $p = 0.06$). The only common gene was *small G protein signaling modulator 3 homolog* (LOC100644967) which shows paternal allele hypermethylation of a CpG and is also hypermethylated in reproductive workers compared to sterile workers but is not differentially expressed between worker castes. Additionally none of the genes identified here containing a parent-of-origin methylated CpG also show allele-specific methylation in a previous

data-set from Chapter 3.

5.5 Discussion

Using whole genome bisulfite sequencing I have identified specific CpGs showing consistent parent-of-origin methylation across two sets of reciprocal crosses. I have additionally identified methylation differences between queens and males and determined there is no relationship between the parental methylation of a gene and allele-specific methylation in reproductive worker offspring. Finally I found no allelic-methylation differences in genes previously shown to exhibit parent-of-origin expression. These results do not support the hypothesis that *cis*-acting DNA methylation is the imprinting mark for genes with parent-of-origin expression. It may be that *trans*-acting DNA methylation may interact with other epigenomic mechanisms, such as histone modifications, to produce parent-of-origin expression. It may also be that other molecular mechanisms, such as non-coding RNAs, play a role.

Eight genes have been identified containing at least one CpG site which exhibits parent-of-origin methylation. However, none of these eight genes also show parent-of-origin expression, as identified in Chapter 4. The genes containing a parent-of-origin methylated CpG had enriched GO terms relating to the ecdysone pathway. Ecdysone is a chemical involved in the ovary activation of reproductive workers (Geva *et al.*, 2005), and multiple genes involved in this pathway have been shown to exhibit allele-specific expression in a previous study using *B. terrestris* workers (Amarasinghe *et al.*, 2015). These findings suggest that if methylation plays any role in parent-of-origin expression, it is an indirect role. This is supported by the identification of a gene involved in chromatin remodelling, which contained CpGs with parent-of-origin methylation, all in exonic regions. Condensed chromatin, or heterochromatin, results in the silencing of genes and has been associated with imprinted genes in mammals (Voon *et al.*, 2015). It has also been shown that, in some species, methylation can influence ncRNAs, which proceed to silence genes in other regions of the chromosome (Barlow, 2011). If this process was occurring in *B. terrestris*, it would explain the lack of consistency between

allelic-methylation and allelic-expression.

The lack of consistency between genes showing parent-of-origin expression from Chapter 4 and parent-of-origin methylation may also be due to the use of independent reciprocal crosses and individuals. It has been previously shown that methylation can vary dramatically between biological replicates (colonies) of the same sub-species of *B. terrestris* (Chapter 2). It may therefore also be possible parent-of-origin methylation and expression may be linked but the genes affected are not conserved across the species. This idea does not support the kinship theory (Haig, 2000) of genomic imprinting, that predicts imprinted genes should be involved in the same functions across individuals within a species. Additionally the lack of overlap of genes with parent-of-origin methylation and differentially methylated genes between reproductive castes from Chapter 2 and lack of overlap with genes showing general allele-specific methylation from Chapter 3 also casts doubt on the kinship theories predictions for imprinted genes in bumblebees. However, these results do support the notion that methylation may offer a dynamic mechanism of plasticity, by being highly variable across colonies and between individuals, as discussed in Chapter 2.

Additionally it is worth noting the analyses done here do not take into account all *cis*-effects (the effect of genotype). Whilst *cis*-effects have been minimised in this study, by the stringent determination of parent-of-origin methylated CpGs (i.e. using individuals from all crosses as replicates within the logistic regression model, and additionally using crosses from closely related individuals), it is still possible *cis*-effects exist within the data. Previous research has found the sequence of an allele can determine the methylation status of a CpG, either by a substitution of a cytosine base with another base or by a long-distance method (Remnant *et al.*, 2016), such as chromatin modification or recruitment/expulsion of DNA binding proteins (Tycko, 2010). More specifically Wedd *et al.* (2016) found polymorphic differences in the *AmLAM* gene in *A. mellifera* were strongly correlated with the overall methylation level of the gene. Re-generation of these data using independent replicates of the reciprocal crosses used here, along with parental and offspring whole genome sequencing, to identify SNPs, would allow for a greater understanding of the role of genotype.

This work can also be improved by increasing the coverage obtained during sequencing. Previous research has suggested coverage as low as 12X can allow for allelic bias in the read sets (Remnant *et al.*, 2016), where one allele shows greater coverage than the other. The logistic regression model used here relies heavily on coverage, with the average coverage per base being approximately 11X. Whilst stringent filtering ensured minimum false positives, it is likely our data contains many false negatives owed to the lack of coverage per base. In order to obtain a more reliable picture of the relationship of parent-of-origin methylation and parent-of-origin gene expression, ideally, this experiment would be repeated using data from the same reciprocal crosses with sequencing carried out to a greater depth.

In order to identify the relationship between parent-of-origin methylation and parental methylation of a gene, methylation differences between queens and males were determined. As this is the first data set to examine methylation at base-pair resolution for *B. terrestris* queens and males, genome methylation patterns were assessed. Reproductive workers and queens show a similar CpG methylation pattern compared to males, this is also the case in some other social insects, such as the fire ant, *Solenopsis invicta* (Glastad *et al.*, 2014). However, this pattern is not uniform across social insects; Bonasio *et al.* (2012) found queens had less methylation compared to males and workers in two species of ant, *Camponotus floridanus* and *Harpegnathos saltator*. Additionally castes of the termite, *Zootermopsis nevadensis*, cluster together with gender nested within clusters, when whole genome methylation patterns are assessed (Glastad *et al.*, 2016). Finally the honeybee *A. mellifera* appears to show more genomic methylation in queens compared to workers (Lyko *et al.*, 2010), indicating social insects have varying methylation differences between castes.

Differentially methylated genes between queens and males were involved in a variety of processes including spermatogenesis, dosage compensation and chromosome organisation. This suggests methylation may play an active role in the generation of the male phenotype. Experimental work to alter methylation in specific genes/regions, by using the CRISPR-cas9 system, as described in Vojta *et al.* (2016), could aid better understanding of the role of methylation in haplodiploid systems. There were no differentially methylated sites between workers and queens/males, this is likely due to the

high level of relatedness between samples, which was taken into account as a covariate within the model. As mentioned previously high inter-colony variation in methylation exists in *B. terrestris* (Chapter 2). Methylation differences between castes and genders could be better assessed using samples designed specifically for this question.

The methylation differences identified between parents were not reflected in the parental alleles of the offspring. This indicates methylation may be wiped and re-established during development, as is seen in mammals (Messerschmidt *et al.*, 2014). Previous research using *A. mellifera* found extreme differences in methylation between eggs, sperm and males (Drewell *et al.*, 2014), with males showing less overall methylation compared to the gametes. Drewell *et al.* (2014) suggest these patterns indicate a series of gains and losses of methylation during development. This would account for the lack of consistency observed here between parental genes and offspring alleles. Future research investigating methylation dynamics throughout development, including adults and gametes is needed.

Overall this study is the first to identify consistent CpG sites showing parent-of-origin methylation in *B. terrestris*. I found no relationship between parent-of-origin methylation and parent-of-origin expression, this indicates methylation is not the imprinting mark driving parent-specific allelic expression. However, numerous limitations of this study may also have influenced these results, such as: *cis*-effects, epigenetic variation between colonies and low genome coverage. Nevertheless, this study has still provided a basis for future work into: the role of methylation in dosage compensation in males and investigations exploring the dynamic nature of methylation during development.

Chapter 6

Variation of DNA methylation in naturally occurring temporal populations of the water flea, *Daphnia magna*, to environmental stressors.

Hollie Marshall, Eamonn Mallon, Leda Mirbahai and Luisa Orsini.

6.1 Abstract

Species employ a variety of mechanisms in order to cope with environmental change, such as: migration, tolerance and adaptation in the form of phenotypic plasticity and/or genetic adaptation. The new field of adaptive epigenetics suggests DNA methylation can provide an additional layer of information upon which selection and adaptive evolution can act. Previous studies exploring the possibility of adaptive epigenetics have utilised a space-for-time design due to the long term nature of multi-generational studies. However, these types of studies are confounded by uncontrolled environmental differences. In this study I overcome these issues by utilising resurrection ecology to study epigenomic changes through evolutionary time. Individual *Daphnia magna* from four historical time periods of a lake with documented environmental change were resurrected. Whole genome bisulfite sequencing of the clonal offspring was carried out in order to identify temporal sub-population differences in DNA methylation. I have found that the temporal sub-populations which experienced eutrophication and high levels of pesticide exposure have less methylation compared to temporal sub-populations under less stressful conditions. I have additionally identified differentially methylated genes between temporal sub-populations. Some of these genes are involved in the production of males, which is a known stress response in this species. These results show DNA methylation can change at the population level through evolutionary time, possibly in response to environmental chance. These finding lays the groundwork for future experiments to determine how DNA methylation may provide an adaptive phenotype.

6.2 Introduction

Anthropogenic impacts on the natural environment are increasing in line with human population growth (Rosenzweig *et al.*, 2008). Of particular concern are freshwater ecosystems, due to the high biodiversity they harbour and their use as a freshwater resource for people. Severe eutrophication and pesticide exposure due to agricultural run-off and pollution are thought to be the next biggest threats to freshwater ecosystems, after destruction due to land-use change (Gopal, 2005). Species employ a variety of mechanisms in order to cope with environmental change, such as: migration, tolerance and adaptation in the form of phenotypic plasticity and/or genetic adaptation.

Adaptive epigenetics is a relatively new field of research (Verhoeven *et al.*, 2016). Epigenetic adaptations can come in the form of: short term temporary responses (epigenetic plasticity), long term permanent responses and heritable permanent responses (epigenetic adaptation) (Weyrich *et al.*, 2015). Research has focused on DNA methylation as it has been suggested that it can provide an additional layer of information upon which selection and adaptive evolution can act (Richards *et al.*, 2010).

In mammals, DNA methylation undergoes a cycle of erasure and reprogramming during development (Messerschmidt *et al.*, 2014). This has questioned the heritability of adaptive epigenetic marks. However, imprinted genes display heritable epigenetic marks which are specific to the parent from which they were inherited from (Barlow and Bartolomei, 2014). These marks escape the general reprogramming cycle, showing the possibility of heritable epigenetics. Additionally, some DNA methylation is caused by the underlying genetic code, these loci are known as epialleles (Meaburn *et al.*, 2010). Epialleles can also be considered heritable epigenetic marks as they are later re-established after developmental erasure.

It is thought changes in DNA methylation in response to the environment may contribute to later genetic adaptation. The presence of DNA methylation has been associated with an increased rate of C/T SNP substitutions which occur through spontaneous deamination (Flores *et al.*, 2013). Flores *et al.* (2013) propose environmentally induced DNA methylation, that is beneficial in terms of survival and reproduction, will remain

present in individuals when the environment is constant. This will lead to an increase in C/T mutations which may facilitate maintenance of the phenotype produced originally by the DNA methylation. Whilst this particular theory is difficult to test, given the long-term nature of the type of study needed, there are multiple other studies detailing short term plastic changes in DNA methylation in response to environmental stressors. These studies span a variety of species, for example: *Arabidopsis thaliana* (Dowen *et al.*, 2012), stickleback (Artemov *et al.*, 2017) and corals (Dixon *et al.*, 2018). Additionally, permanent epigenetic differences between locally adapted populations have also been identified in: *A. thaliana* (Kooke and Keurentjes, 2015), bats (Liu *et al.*, 2015), oak trees (Platt *et al.*, 2015), chickens (Zhang *et al.*, 2017) and stickleback (Heckwolf *et al.*, 2019).

Many of the studies mentioned above either focus on a single experimental generation or utilise the ‘space-for-time’ method, whereby spatially separated populations under different environmental conditions are used as a proxy to try to understand how species adapt to environmental change. However, it is difficult to take all naturally occurring variables into account with this method and so observing adaptation in a single population over time is preferable. Observing adaptation through time often involves long-term studies across multiple generations, of which there are few, see Grant and Grant (2002) as a rare example. Resurrection ecology provides a means of observing temporal adaptation within the same population by utilising dormant life stages such as seeds or eggs from dated sediment cores (Kerfoot *et al.*, 1999), avoiding the long-term nature of such studies.

The freshwater crustacean, *Daphnia magna*, produces a dormant life stage which can be hatched after hundreds of years of dormancy, with the oldest resurrected individual dated to around 700 years old (Frisch *et al.*, 2014). *D. magna* provide an ideal study system to explore the potential role of epigenetic adaptation in response to anthropogenic stressors. Firstly, *D. magna* reproduces clonally during its life cycle (Fig. 6.1) and it is easily cultured in the lab, allowing a particular ‘genotype’ (i.e. a line of genetically identical offspring from a resurrected individual) to be maintained. Additionally, each resurrected individual is sexually produced and so provides a unique genetic line (Fig. 6.1). Previous research has found resurrected individuals provide a genetically

representative sample of temporal populations (i.e. a population of individuals sampled from a given time period) obtained from dated sediment cores (Orsini *et al.*, 2016).

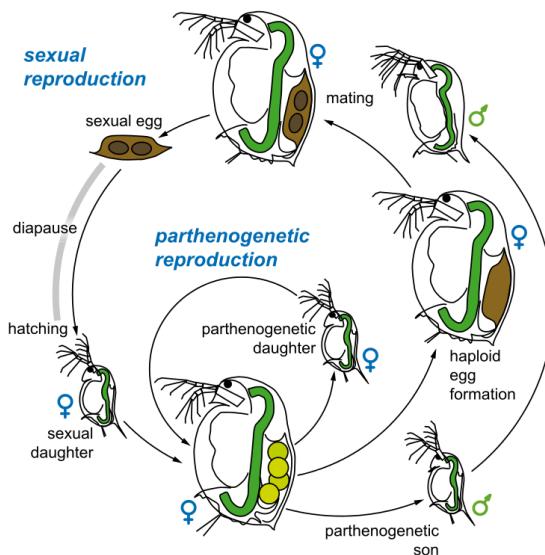

Figure 6.1: *Daphnia magna* life cycle. *Daphnia* exhibit cyclic parthenogenesis. Under stable environmental conditions females reproduce clonally. Under stressful conditions they produce males and sexual haploid eggs which are fertilised to produce a ‘resting’ life stage. These sexual eggs will eventually hatch into a genetically distinct female. Image credit: Dita Vizoso, source: http://scierceresourcebox.co.nz/blog/post&post_id=24.

D. magna also has a fully functional DNA methylation system, with methylation primarily found in gene bodies and associated with higher gene expression (Kvist *et al.*, 2018). Additionally, single-site CpG methylation levels have been reported between 0.7-1.7% (Kvist *et al.*, 2018; Hearn *et al.*, 2019), which is also similar to some insect species (Bewick *et al.*, 2016), such as *Bombus terrestris* which shows around 0.7% CpG methylation (Chapter 2).

The methylome of *D. magna* has been shown to be responsive to changes in environmental conditions. For example: sex-determination and sexual reproduction are the product of epigenetic changes caused by stressful conditions (Harris *et al.*, 2012), the presence of predators induces epigenetic changes which alter the phenotype (Asselman *et al.*, 2015) and calorie restriction alters genome-wide CpG methylation (Hearn *et al.*, 2019). Transgenerational effects on DNA methylation induced by chemical exposure (Vandegehuchte *et al.*, 2010) and salt stress (Jeremias *et al.*, 2018) have also been documented. Jeremias *et al.* (2018) found that changes in methylation after salt stress

persisted until the F3 generation, indicating adaptive epigenetic heritability. These studies show the potential of *D. magna* as a model organism for adaptive epigenetic research.

The study presented here will utilise whole-genome bisulfite sequencing and resurrection ecology to identify stable epigenetic changes in 40 genotypes from a temporal population of *D. magna*. Each temporal sub-population (i.e. a population of individuals sampled from a given time period from the same spatial population) was historically exposed to different anthropogenic stressors. I hypothesise differences in DNA methylation between sub-populations which historically experienced anthropogenic stress and those which did not experience anthropogenic stress. This is the first study, to my knowledge, to combine the power of resurrection ecology and the benefits of *D. magna* as a epigenetic model organism to identify potential adaptive epigenetic changes in DNA methylation, through time, in response to environmental stress in a natural population.

6.3 Methods

6.3.1 Sample origin

Individual genotypes used in this study originate from sediment cores taken from Lake Ring in Mid Jutland, Denmark ($55^{\circ}57'51.83''$ North, $9^{\circ}35'46.87''$ East, Fig. 6.2).

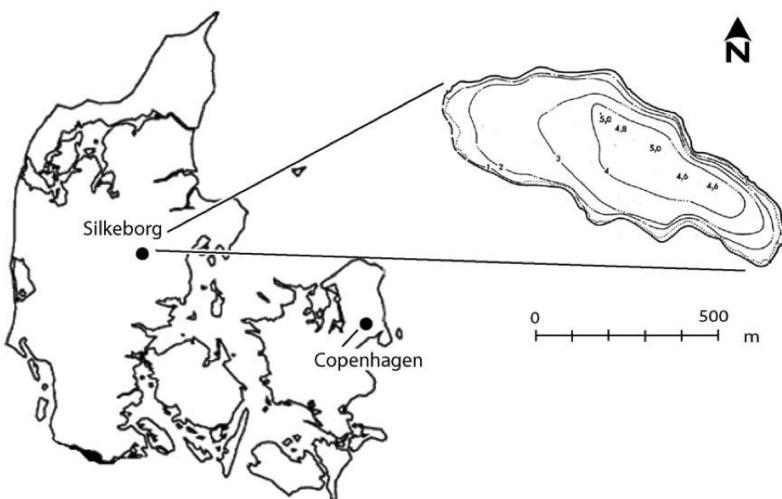

Figure 6.2: Image adapted from Berg *et al.* (1994) and Michels (2007), location of Lake Ring in Denmark and a depth profile in meters.

This lake has a well characterised history; in the 1950s eutrophication occurred due to sewage inflow from a nearby town, this was diverted towards the end of the 1970s (Berg *et al.*, 1994). During the 1980s agricultural land-use increased causing pesticide contamination within the lake (Cuenca Cambronero *et al.*, 2018). Additionally, an invertebrate predation study was carried out in the lake during 1989-1990 where the lake was stocked with white fish (Berg *et al.*, 1994) and was then observed to partially recover from eutrophic conditions post-1989 (Michels, 2007). These well documented periods allow the lake to be split into four distinct phases (Fig. 6.5).

Isolated ephippia (dormant sexual eggs) were hatched from each of the phases from radiometric-dated sediment cores taken from the lake, as described in Cuenca Cambronero *et al.* (2018). Previous research has generated whole genome and transcriptome sequencing for individuals from the all lake phases (unpublished, Orsini Lab, University of Birmingham). The same genotypes were selected for this study. They consist of 11 genotypes from the recovery phase, 10 from the pesticide phase, 9 from the eutrophic phase and 10 genotypes from the pristine phase (Fig. 6.3 and supplementary 6.0.0). Previous work has found that 10 genotypes are sufficient to provide a representative sample of the genetic diversity within a population of *D. magna* (Orsini *et al.*, 2016).

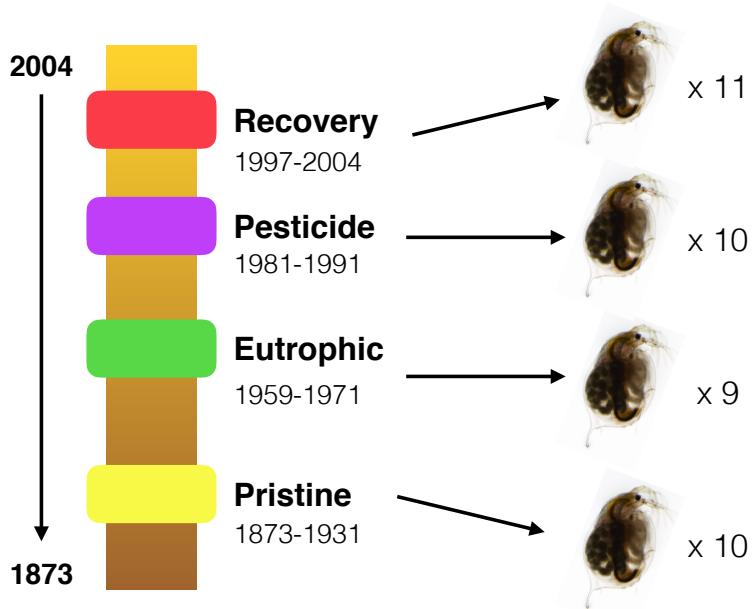

Figure 6.3: Nine to eleven *Daphnia magna* genotypes were selected as temporal sub-population replicates from the four phases of Lake Ring. Dates show are exact date ranges for the specific genotypes selected, as dated from the sediment cores taken from Lake Ring.

6.3.2 *Daphnia* husbandry and sampling

The original resurrected genotypes were hatched in 2014, as described in Cuenca Cambonero *et al.* (2018). Clonal lines have since been maintained in lab conditions, consisting of: bore-hole water, 10°C, *ad libitum* *Chlorella vulgaris* algae (0.8mg C/L) and a light:dark regime of 16:8hrs. Individuals from all 40 genotypes were cultured in control conditions for a minimum of two generations prior to sample collection in order to reduce maternal effects from previous culturing in the 10°C stock room. Conditions consisted of: 20°C, *ad libitum* *Chlorella vulgaris* algae (0.8mg C/L) and a light:dark regime of 16:8hrs. Samples were maintained in high-hardness COMBO medium (Appendix D.1) through out the experiment and the medium was changed three times per week.

After two generations of acclimation, three to five individuals were placed in 250ml jars (Fig. 6.4a). Neonates <24hrs produced from the 3rd-10th brood were cultured

in a new 1L jar (Fig. 6.4a) until they reached four days old (pre-ovary development). The sex and developmental stage of each individual was determined using a dissecting microscope and groups of 20 individuals per genotype (Fig. 6.4b) were flash frozen in liquid nitrogen between 9am-1pm. A strict time period was applied to control for any potential circadian effects on methylation (Pegoraro *et al.*, 2016). A total of 100-200 individuals were used for DNA extraction in order to obtain enough DNA for sequencing. The number of individuals varies per sample as it was not possible to count the number of *Daphnia* per sample and stay within the 9am-1pm time window.

Figure 6.4: (a) experimental set-up, black lidded jars are the 250ml jars containing the experimental *Daphnia magna* mothers and the white lidded jars are the 1L jars containing the juveniles. (b) a typical sample of healthy 4-day old juvenile female *D. magna*.

6.3.3 DNA extraction and sequencing

Tissue lysis was carried out using a 2025 Geno/Grinder[®] (SPEX SamplePrep). The Epicenter MasterPureTM Complete DNA and RNA Purification Kit was used following a modified protocol (Appendix D.2) to extract genomic DNA from 100-200 four day old females, per genotype. DNA quantity was assessed using a Qubit[®] fluorometer and quality was visualised using a 1% agarose gel. Sample preparation took place in the UoB Environmental Omics Sequencing Facility. All DNA samples were sent to BGI Tech Solution Co., Ltd.(Hong Kong) for bisulfite library preparation and sequencing. Directional bisulfite libraries were prepared by fragmenting genomic DNA to 100-300bp

by sonication, DNA-end repair was then carried out along with ligation of methylated sequencing adaptors. The ZYMO EZ DNA Methylation-Gold kit was used for bisulfite treatment with subsequent desalting, size selection, PCR amplification and final size selection before sequencing. RNA-seq libraries were prepared by using magnetic beads with an Oligo (dT) to enrich for mRNA, the mRNA was then fragmented and cDNA was synthesised using random hexamer priming, size selection and PCR amplification were then carried out prior to sequencing. A 1% unmethylated lambda spike was included in each sample in order to assess later bisulfite conversion rates. Samples were then sequenced across six lanes (along with 30 other *Daphnia* samples from a related project) on an Illumina HiSeq 4000 using 150bp paired-end reads.

6.3.4 Differential methylation

Data quality were checked using fastqc v.0.11.5 (Andrews, 2010) and trimmed using CutAdapt v1.1 (Martin, 2011). Trimmed data were aligned to the reference assembly (daphmag2.4, GenBank accession: GCA_001632505.1) using Bismark v.0.16.1 (Krueger and Andrews, 2011) and bowtie2 v.2.2.6 (Langmead and Salzberg, 2012) with default parameters. Alignment output files were deduplicated using Bismark v.0.16.1 (Krueger and Andrews, 2011) and sorted and indexed using samtools v.1.3.2 (Li *et al.*, 2009).

The R package *methylKit* (Akalin *et al.*, 2012) was used to determine differentially methylated CpG sites between temporal populations. In order to determine how the methylation profile changes across time to given environmental stressors, sequential pair-wise comparisons were used. For each data pair, coverage outliers (above the 99.9th percentile) were removed along with bases covered by less than 10 reads. The methylation status of each CpG was then determined, using the ‘methylation status calling’ (MSC) procedure, as described in Cheng and Zhu (2014). CpG sites were then filtered to remove any site that did not return as methylated in at least one sample per comparison. A logistic regression model was then applied to the remaining CpG sites with Benjamini-Hochberg multiple testing correction (Benjamini and Hochberg, 1995). Sites were determined as differentially methylated between temporal populations if they exhibited a minimum difference of at least 10% and a q-value of <0.05.

Genes were determined as differentially methylated genes if they contained at least one differentially methylated CpG and had an overall weighted methylation difference of >10%. Weighted methylation level was determined as the total number of methylated cytosines (C) within a region (i), divided by the total coverage of a region (Equation 6.1), as described in Schultz *et al.* (2012).

$$\sum_{i=1}^n C_i / \sum_{i=1}^n C_i + T_i \quad (6.1)$$

6.3.5 Gene ontology enrichment

Gene ontology (GO) terms for *D. magna* were obtained from http://arthropods.eugenes.org/EvidentialGene/daphnia/daphnia_magna/Genes/function/cddrps-dapmaevg14.gotab2. GO enrichment analysis was carried out using the hypergeometric test with Benjamini-Hochberg (Benjamini and Hochberg, 1995) multiple-testing correction, $q < 0.05$. GO terms associated with differentially methylated genes between temporal population were assessed for enrichment against GO terms associated with all methylated genes within the *D. magna* assembly. Genes were classed as methylated if they had a mean weighted methylation level greater than the bisulfite conversion error rate of >0.05 in at least one temporal population. REVIGO was used for GO term visualisation (Supek *et al.*, 2011).

All bioinformatic scripts used within this chapter can be found at: <https://doi.org/10.5281/zenodo.3235644>.

6.4 Results

6.4.1 DNA extraction

DNA extracted from 100-200 four-day old *D. magna* gave a suitable quantity for whole genome bisulfite sequencing (supplementary 6.0.1). All DNA samples showed some level

of degradation. However, they all also had a band >10,000bp and so met the minimum requirements for sequencing.

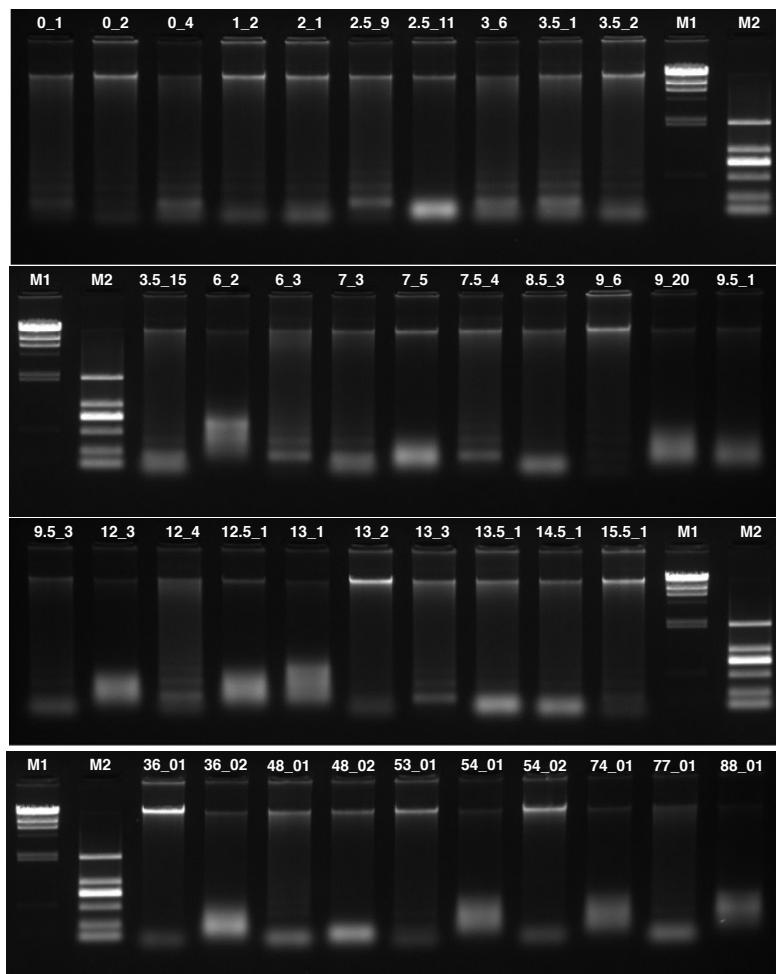

Figure 6.5: 1% agarose gel of all extracted *Daphnia magna* samples with ladders M1 and M2. Each sample label refers to the unique genotype.

6.4.2 Data quality

The average alignment rate to the daphmag2.4 reference genome was $48.1\% \pm 2.67\%$ (mean \pm standard deviation), which corresponds to $8,715,797 \pm 1,301,722$ uniquely mapped reads. The average PCR duplication rate was $25.87\% \pm 2.02\%$. After removal of PCR duplicates the final coverage was $12.9X \pm 1.8X$ (supplementary 6.0.2). From alignment to the lambda genome, the bisulfite conversion efficiency was determined as $99.6\% \pm 0.14\%$. Using this error rate methylation was only identified in a CpG

context, with an average single-site methylation level of $0.5\% \pm 0.11\%$ across all samples (supplementary 6.0.2).

6.4.3 Genome-wide methylation differences between temporal temporal populations

Temporal populations do not cluster when CpG methylation is plotted (Fig. 6.6a). However, a PCA plot using the same data shows the genotype; 3.5_15, clusters away from all other samples (Fig. 6.6b). The single-site methylation level for this genotype is also more than double the mean of all samples, 1.1% compared to 0.5% respectively (supplementary 6.0.2).

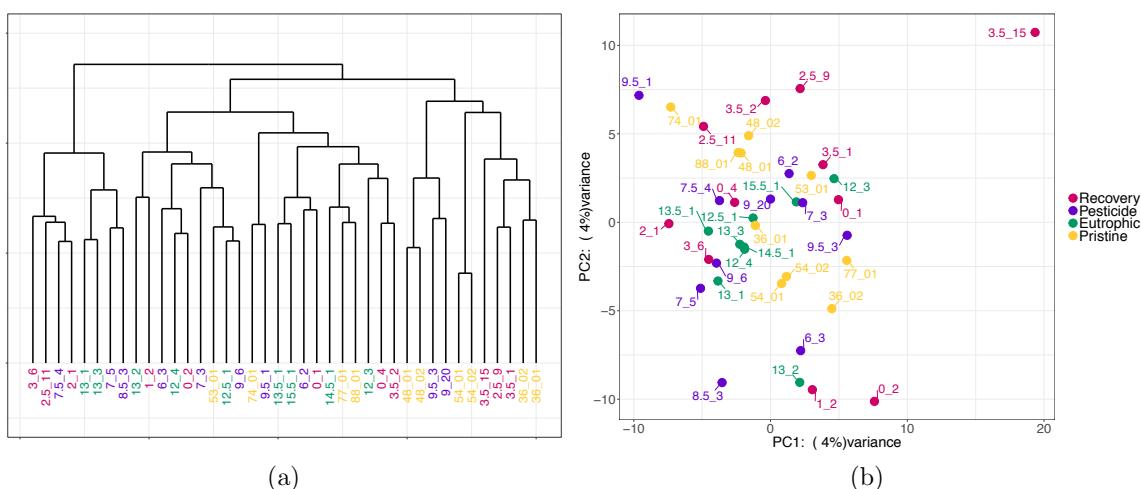

Figure 6.6: (a) Hierarchical cluster based on methylation correlation distances of all CpG sites methylated in at least one *Daphnia magna* sample ($N = 3,938$), calculated using the ‘ward’ method. (b) PCA plot generated using all CpG sites methylated in at least one sample.

There is a significant difference in the weighted methylation level of methylated genes across temporal populations (Kruskal-Wallis: chi-squared = 38036, df = 2, p <0.000, Fig. 6.7). The eutrophic and pesticide populations have a lower weighted methylation level across methylated genes compared to the pristine and the recovery populations (Table 6.1). However, there is no difference between the recovery and the pristine population, or between the pesticide and eutrophic population (Table 6.1).

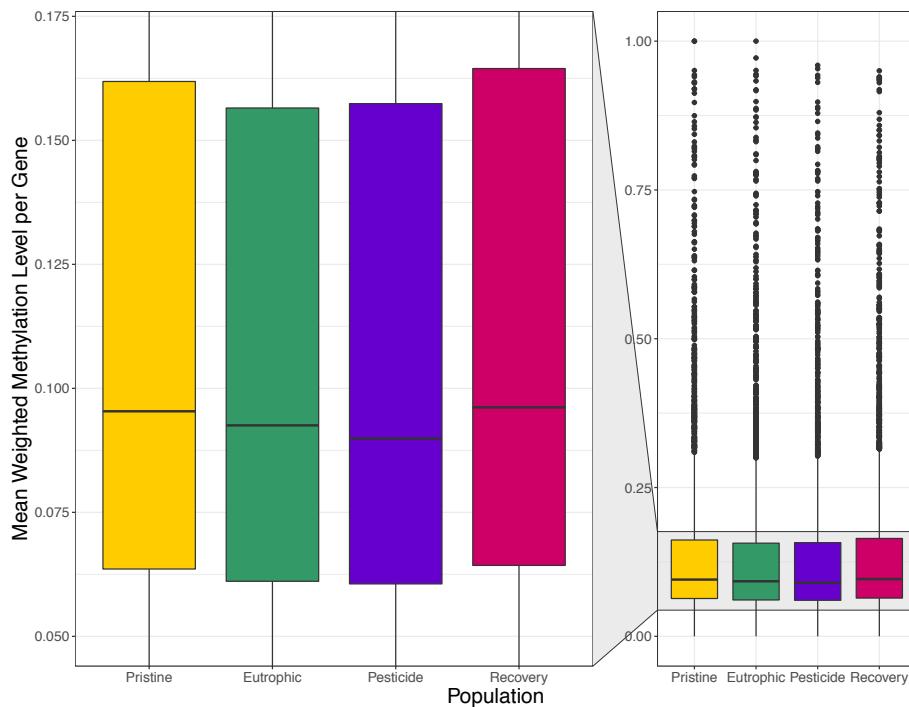

Figure 6.7: Right: boxplot showing the weighted methylation level of methylated genes ($N = 3,563$) for all temporal sub-populations of *Daphnia magna*. Each boxplot shows the median along with the 25th and 75th percentile. The whiskers represent 1.5X the interquartile range. Outliers are represented as additional black points. Left: an enlarged view of the interquartile range.

Table 6.1: Dunn's test post-hoc comparisons of weighted methylation level across all methylated genes between populations. P-values have been adjusted for multiple testing using the Benjamini-Hochberg method (Benjamini and Hochberg, 1995). * indicates a significant p-value < 0.05 .

Comparison	Z	Adjusted p-value
eutrophic - pesticide	0.9495285	0.411
eutrophic - pristine	-2.1803658	0.043*
pesticide - pristine	-3.1296273	0.005*
eutrophic - recovery	-3.0935671	0.003*
pesticide - recovery	-4.0430289	0.000*
pristine - recovery	-0.9124847	0.362

6.4.4 Differentially methylated genes between populations

The majority of differentially methylated CpGs between populations were located within a gene (Table 6.2, supplementary 6.0.3 - 6.0.5). Genes containing at least one

differentially methylated CpG were filtered to provide a list of differentially methylated genes which also have a weighted methylation difference of >10% (Table 6.2, supplementary 6.0.6 - 6.0.8). Only sequential pair-wise comparisons were carried out to identify DNA methylation differences through time. Future research could pose new hypotheses based on specific environmental differences between sub-populations which would then require other sub-population comparisons.

Table 6.2: Table showing the number of CpGs tested for differential methylation between populations after filtering on coverage and to ensure each CpG is methylated in at least one sample. The number of differentially methylated genes between populations and the number found within a gene and outside of a gene are also shown. The filtered genes column refers to the number of genes with at least one differentially methylated CpG and a weighted methylation difference >10%.

Comparison	CpGs tested	Differentially methylated CpGs	Located within a gene	Located outside of a gene	Filtered genes
Pristine vs Eutrophic	1,970	194	164	30	79
Eutrophic vs Pesticide	1,970	191	160	31	71
Pesticide vs Recovery	2,612	299	268	31	115

The pristine population has significantly more hypermethylated genes (i.e. genes with higher methylation) compared to the eutrophic population, 55 and 24 respectively (Chi-squared goodness of fit: $\chi^2 = 12.165$, df = 1, $p < 0.000$). The pesticide population also has more hypermethylated genes compared to the eutrophic population, 48 and 23 respectively (Chi-squared goodness of fit: $\chi^2 = 8.8028$, df = 1, $p = 0.003$). Finally, the recovery population has more hypermethylated genes compared to the pesticide population, 75 and 40 respectively (Chi-squared goodness of fit: $\chi^2 = 10.652$, df = 1, $p = 0.001$).

3,563 genes had a weighted methylation level greater than the bisulfite conversion error rate of 0.05%. Of these, 2,561 had annotated gene ontology terms. There were only 26 genes from the 76 differentially methylated genes between the pristine and eutrophic populations that had annotated GO terms. Significantly enriched GO terms for these genes compared to all methylated genes included a variety of terms (supplementary 6.0.9), such as *oogenesis* (GO:0048477) and *mRNA 3'-end processing* (GO:0031124).

Of the 71 differentially methylated genes found between the eutrophic and the pesti-

cide population, 26 had annotated GO terms. As above, enriched GO terms included a variety of biological processes (supplementary 6.1.0), such as *oocyte development* (GO:0048599) and *stem cell differentiation* (GO:0048863).

There were slightly more differentially methylated genes between the pesticide and the recovery population, that were annotated with gene ontology terms, 40/115. These were also diverse but were significantly enriched for processes relating to DNA repair and protein modifications (supplementary 6.1.1), including *histone H2A K63-linked deubiquitination* (GO:0070537).

6.4.5 Similarity between differentially methylated genes

There are 205 unique genes differentially methylated across temporal populations. Almost half of these are unique to the differentially methylated genes found between the pesticide and the recovery population (Fig. 6.8). There is a significant overlap of differentially methylated genes between the eutrophic/pesticide comparison and the pristine/eutrophic comparison (hypergeometric test, $p < 0.000$, Fig. 6.8, supplementary 6.1.2). Within these overlapping genes 21/36 are hypomethylated in the eutrophic population compared to both the pristine and the pesticide populations, 11 are hypermethylated in the eutrophic population compared both to the pristine and the pesticide populations and four are variable.

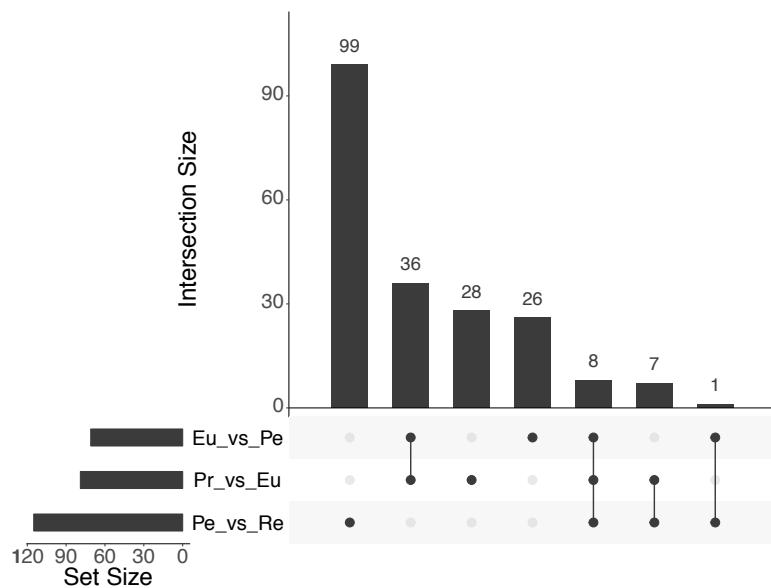

Figure 6.8: UpSet plot showing the number of common differentially methylated genes between *Daphnia magna* sub-population comparisons. Eu = eutrophic, Pe = pesticide, Pr = pristine and Re = recovery. The set size indicates the number of genes in each category. The intersection size shows how many genes the corresponding lists, represented by the jointed dots in the lower panel, have in common. A single dot in the lower panel refers to the number of genes unique to each list.

There are eight genes which are differentially methylated in every comparison across temporal populations (Fig. 6.8, supplementary 6.1.2). There is no apparent trend in the methylation changes for these genes across evolutionary time (Fig. 6.9). Additionally, these genes have some GO terms associated with the generation of males (Fig. 6.10).

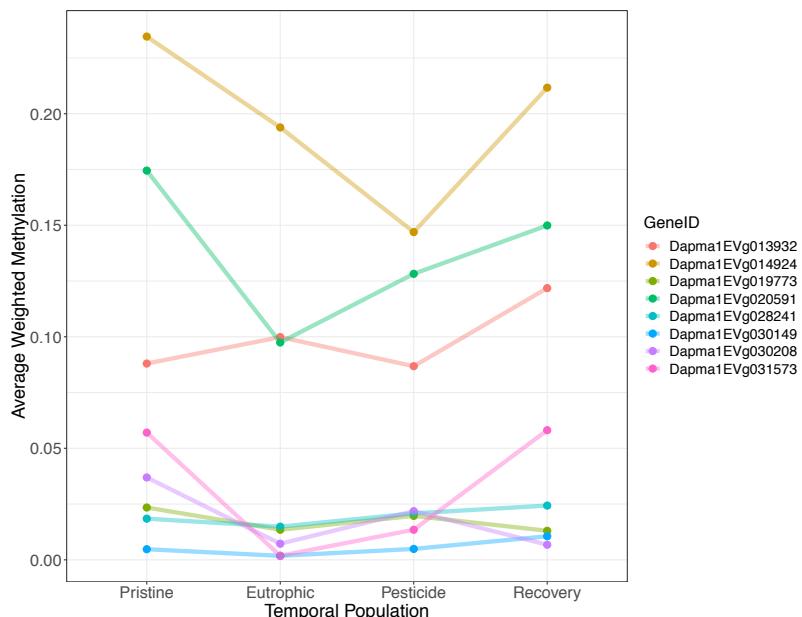

Figure 6.9: The average weighted methylation for each temporal sub-population of *Daphnia magna* for the eight genes which are differentially methylated in every comparison.

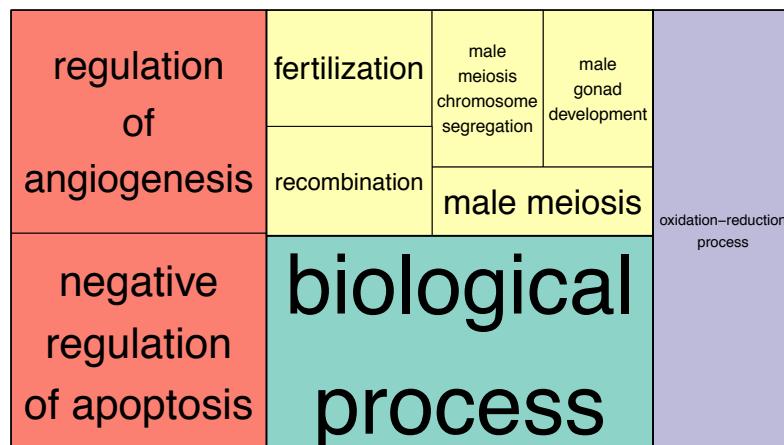

Figure 6.10: Treemap showing GO terms associated with the eight genes which are common amongst all differential methylation comparisons between each *Daphnia magna* sub-population comparison. Each rectangle represents a cluster of related terms, with linked clusters indicated by colour. The size of the rectangle represents uniqueness within each cluster.

6.5 Discussion

This study is the first to identify stable methylation changes in naturally occurring temporal populations of *D. magna*. Using whole genome bisulfite sequencing I have found temporal populations are generally homogeneous in terms of their CpG methylation profiles. However, populations previously exposed to anthropogenic stressors have lower methylation levels in methylated genes compared to unexposed populations. I have also identified differentially methylated genes between temporal populations and found genes which exhibit changes in methylation over evolutionary time.

The single-site methylation level identified here is slightly lower than previously reported for this species, 0.5% compared to 0.7-1.7% (Jeremias *et al.*, 2018; Kvist *et al.*, 2018; Hearn *et al.*, 2019). However, these previous studies have all used a single lab-standard genotype. Here, all sample levels range from 0.4-0.6% except for the genotype; 3.5_15 (from the recovery population) which has a single-site methylation level of 1.1% and clusters away from all other samples in a PCA analysis. This particular genotype was also observed to have much larger broods throughout the experiment, although no numerical data were collected. Previous research using *D. magna* has also identified different phenotypic responses to chemical exposure in five different standard lab genotypes (Baird *et al.*, 1991). This new finding of large methylation differences amongst individuals, along with previous work showing different responses to stressors across genotypes, confirms the importance of using multiple genotypes within an experiment in order to draw population/species level conclusions.

When the methylation level of only methylated genes is assessed, the eutrophic and pesticide populations have lower methylation levels compared to the pristine and recovery populations. Some previous work has found no difference in global methylation levels when the same genotype is exposed to environmental stress (Jeremias *et al.*, 2018; Hearn *et al.*, 2019). However, Vandegehuchte *et al.* (2009) found a decrease in global methylation in *D. magna* after zinc exposure which persisted for one additional generation. As these individuals were maintained in control conditions, the differences in methylation levels observed are likely due to inherited methylation differences, rather

than as a response to the culturing environment. However, it is worth noting that populations/genotypes may respond differently to control conditions (Baird *et al.*, 1991). The conditions used here are likely to be more similar to those experienced by the pristine population, and novel to the other temporal populations. Whilst the clonal lines used in this study have been maintained for many generations within the lab, future work could attempt to replicate the natural environment experienced by each population to examine if the methylome responds differently to historical conditions compared to control culturing conditions.

As well as a difference in the methylation level of methylated genes, there are numerous differentially methylated genes between temporal populations. Differentially methylated genes between the pristine and eutrophic population and between the eutrophic and pesticide population are enriched for GO terms related to reproduction, amongst other terms. It has been well documented that exposure to environmental stressors in *D. magna* affects both fecundity and reproductive timing (e.g. Brown and Yan, 2015; Blinova *et al.*, 2017; Saebelfeld *et al.*, 2017; Sarapultseva *et al.*, 2019). Specifically, Cuenca Cambronero *et al.* (2018) identified fitness responses to environmental stressors, with the same genotypes used here, from the: recovery, pesticide and eutrophic phases. They found temperature and food availability affected fecundity in all three populations and exposure to the pesticide, Carbaryl, caused higher fecundity specifically in the eutrophic population. The identification of potentially permanent methylation changes related to reproduction in *D. magna*, suggests historical exposure to anthropogenic stressors may affect subsequent generations, even after the removal of the stressor. Experimental manipulation of DNA methylation in the eutrophic population, for example via new methods capitalising of the CRISPR/cas system (Vojta *et al.*, 2016), could help to elucidate the relationship between methylation, reproduction and environmental stressors.

The differentially methylated genes identified between the pesticide and recovery population were enriched for multiple GO terms, including GO terms related to histone modifications. DNA methylation has previously been found to signal the recruitment of histone modifications in other species, these modifications can silence genes within a whole genomic region via heterochromatin formation (Barlow, 2011). As DNA methy-

lation is so low in *D. magna*, this epigenetic pathway may provide a mechanism by which DNA methylation can alter the gene expression of multiple genes in response to environmental change. The identification of open chromatin regions via ATAC-seq (Buenrostro *et al.*, 2015) would allow the determination of associations between heterochromatin and DNA methylation.

Whilst enriched GO terms for differentially methylated genes were identified, not all genes within the current daphmag2.4 genome annotation have GO terms assigned. A re-analysis of this data in light of further functional annotation will provide more insight into the role of the differentially methylated genes between temporal populations.

There is a significant overlap in the differentially methylated genes between the eutrophic population and the pristine/pesticide population. The majority of these genes are hypomethylated in the eutrophic population in both comparisons. Previous work has identified large changes in population genetic structure in a population of *Daphnia pulicaria*, in response to historical eutrophication (Frisch *et al.*, 2014). Other work, using the same genotypes as in this study, also found significant differences in the neutral genetic structure between the eutrophic, pesticide and recovery populations (Orsini *et al.*, 2016). This may indicate *D. magna*, in this population, may be using a combination of genetic adaptation and potentially changes in DNA methylation as a means of altering gene expression to cope with environmental stressors. Previous work has associated hypomethylated CpGs with down-regulation of differentially expressed genes, when two genotypes were subjected to various stressors (Kvist *et al.*, 2018). The transcriptomes of the genotypes used here have been generated in a previous study (unpublished, Orsini Lab, University of Birmingham). The identification of the expression patterns exhibited by the hypomethylated genes in the eutrophic population compared to the pristine/pesticide population would elucidate the effect of methylation on the phenotype in this population over time.

Finally, there were eight genes found to be differentially methylated across temporal populations. Whilst there is no apparent trend in the methylation of these genes over time, they are enriched for processes related to sexual reproduction and the creation of males. *Daphnia* reproduce sexually when environmental conditions become

unfavourable (Hebert, 1978). Epigenetic mechanisms, induced by environmental signals, are thought to be the trigger for a change in gene expression of the *doublesex* gene, which leads to male production (LeBlanc and Medlock, 2015). Functional annotation and experimental validation are required to determine if one/some of the genes identified here may play a role in this pathway.

Overall this study has identified methylation differences between temporal populations of *D. magna* which were exposed to different historical conditions. Differentially methylated genes are involved in fitness related traits such as reproduction and the production of males. These differences suggest environmentally induced epigenetic changes, as a consequence of anthropogenic impact, may be heritable in this species, either in the form of epialleles or via direct heritability. Additionally, the varying levels of methylation across individual genotypes highlights the importance of using multiple clonal lines in future studies. Finally, this study lays the groundwork for future experimental validation of the role of DNA methylation in adaptation in this species.

Chapter 7

Overall discussion

7.1 Summary of results and major findings

7.1.1 Methylation and caste determination in *Bombus terrestris*

In Chapter 2 whole genome bisulfite sequencing and RNA-seq from reproductive and sterile *B. terrestris* workers were used to investigate the role of DNA methylation in reproductive caste determination. In order to achieve this I characterised caste specific *B. terrestris* methylomes for the first time. I found they are similar to other holometabolous insects with more highly methylated genes showing higher levels of expression and lower levels of methylation being associated with differentially expressed genes. I found no methylation differences on a genome-wide scale between reproductive castes. However, 111 genes were differentially methylated. These were involved in a variety of functions including reproductive related processes. I found no relationship between genes that are differentially expressed, or contain differential exon usage between castes with those that show differential methylation between castes. Finally I also found no common putative orthologous genes differentially methylated between *B. terrestris* and *A. mellifera* reproductive castes.

This Chapter provides the first insights into the nature of a bumblebee caste-specific methylome as well as its interaction with gene expression and caste-specific alternative splicing, providing greater understanding of the role of methylation in phenotypic plasticity within social bee species. Specifically, DNA methylation does not appear to directly mediate worker reproductive behaviour via changes in gene expression in

B. terrestris. However, given the methylation differences in reproductive genes it may still have an elusive role in reproductive behaviour or be a product of reproductive development.

7.1.2 Genomic imprinting in *Bombus terrestris*

Utilising the data generated in Chapter 2, in Chapter 3 I have identified genome wide allele-specific expression and allele-specific methylation. The majority of genes displaying allele-specific expression are common between reproductive castes and the proportion of allele-specific expression generally varies between colonies. This study has also identified allele-specific methylation differences between reproductive castes and found the majority of allelic-methylation events are located within genes. However, there is no significant overlap of genes showing allele-specific expression and allele-specific methylation. Although, genes with common allele-specific methylation between castes show a higher proportion of allelic-expression bias compared to allelically methylated genes unique to either reproductive or sterile workers.

This Chapter is the first to identify differences in allele-specific expression and allele-specific DNA methylation between reproductive worker castes of *B. terrestris*. There is no significant association between alleleically expressed and alleleically methylated genes indicating *cis*-acting DNA methylation may only play a role in allele-specific expression in a small number of cases. Due to the high amount of allele-specific DNA methylation it may serve to alter gene expression in *trans* and/or by interacting with other epigenetic marks such as histone modifications.

Chapter 4 used parental genome sequencing and offspring RNA-seq to identify genes showing parent-of-origin expression in *B. terrestris*. I predicted higher matrigenic expression bias in queen-less workers, in genes related to reproductive functions, following the predictions of Haig's kinship theory (Queller, 2003; Haig, 2000). There was no difference in the number of genes showing maternal or paternal expression bias in either reproductive or sterile workers. However, genes showing the highest proportion of expression bias were all maternally expressed in both castes. Additionally, reproductive related GO terms were enriched in both maternally and paternally expressed genes

along with multiple other biological processes. Maternally expressed genes also showed significant overlap with differentially expressed genes between reproductive and sterile workers in head tissue. However, there was no significant overlap between genes identified as potentially imprinted in *B. terrestris* and those identified from previous research in *A. mellifera*.

The work from Chapter 4 is the first to identify parent-of-origin expression in *B. terrestris*. Higher maternal expression in queen-less workers is consistent with the predictions of the kinship theory. Additionally, some genes found to show parent-of-origin expression are involved in reproductive related processes, which is also consistent with the kinship theory. However, given the lack of association between genes with parent-of-origin expression and differential expression between castes, potentially-imprinted genes may have additional functions beyond those predicted by the kinship theory. These functions may include adaptation via the regulation of gene expression. However, this hypothesis requires further study.

After the identification allele-specific methylation in Chapter 3 and parent-of-origin expression in Chapter 4, Chapter 5 identified a small number of CpGs which show parent-of-origin allele-specific methylation. In this chapter I have additionally identified differentially methylated genes between queens and males which are enriched for GO terms related to spermatogenesis and chromosome organisation. I have also determined there is no strict relationship between the parental methylation of a gene and allele-specific methylation in reproductive worker offspring. Finally I found no allelic-methylation differences in genes previously shown to exhibit parent-of-origin expression.

To my knowledge, Chapter 5 provides the first evidence for gene-level parent-of-origin DNA methylation in any insect. Due to the lack of association between parent-of-origin DNA methylation and parent-of-origin expression it is clear *cis*-acting DNA methylation is not an imprinting mark in *B. terrestris*. However, as is the case in some imprinted mammalian genes, DNA methylation may be acting in *trans* by altering chromatin accessibility via additional epigenetic marks.

7.1.3 Adaptive methylation in *Daphnia magna*

The final chapter of this thesis, Chapter 6, is the first study to identify stable methylation changes in naturally occurring temporal populations of *D. magna*. Using whole genome bisulfite sequencing I have found temporal populations are generally homogeneous in terms of their CpG methylation profiles. However, populations previously exposed to anthropogenic stressors have lower methylation levels in methylated genes compared to unexposed populations. I have also identified differentially methylated genes between temporal populations and found genes which exhibit changes in methylation over evolutionary time. A small subset of genes which change between each temporal population also have GO terms related to the production of males.

It has been hypothesised DNA methylation may provide an additional layer of information for selection to act upon. The results of this study support this idea. Primarily, the identification of differentially methylated genes involved in male production (a stress response) which correspond to changes in environmental conditions. The results from this Chapter provide the groundwork for future adaptive epigenetic work in *Daphnia magna*.

7.2 Impact on ecological epigenetics as a field

Whilst each results chapter within this thesis has specific implications for the related research field, as detailed in each individual discussion, the overarching discoveries of this work have wider implications for the field of ecological epigenetics.

The overall aim of this thesis was to identify potential roles of DNA methylation in two arthropod species. Given the variety of methylation profiles observed across arthropods, it is likely DNA methylation serves different purposes between species (Thomas *et al.*, 2018). The differences in DNA methylation between reproductive castes of *B. terrestris* suggests a potential role for DNA methylation in caste determination in this species. The influence of DNA methylation on imprinted genes in *B. terrestris* remains unclear. Additionally, differences in DNA methylation over evolutionary time in a sin-

gle population of *D. magna* have been documented, hinting to the adaptive potential of DNA methylation.

It has been suggested DNA methylation plays a role in maintaining the expression of housekeeping genes in arthropods (Gatzmann *et al.*, 2018; Provataris *et al.*, 2018). Sarda *et al.* (2012) found high sequence conservation in highly methylated genes between various invertebrate species. The presence of DNA methylation in highly conserved coding regions in arthropods is in conflict with the high rate of cytosine-thymine mutations generated by DNA methylation through spontaneous deamination. It may be that the benefits of transcriptional stability in housekeeping genes outweigh the costs of a higher cytosine-thymine mutation rate. Alternatively, Park *et al.* (2011) found genes with higher DNA methylation in *Nasonia* species have lower overall mutation rates than those with less DNA methylation, suggesting DNA methylation may serve to protect the sequence from non-CpG mutations.

Whilst the highly methylated genes identified in *B. terrestris* in Chapter 2 also show high expression levels, genes with varying levels of methylation in both *B. terrestris* and *D. magna* have been found to be enriched for GO terms related to a variety of processes throughout this thesis. Dixon *et al.* (2018) believe gene-body methylation may be involved in balancing the expression levels of housekeeping genes with more plastic environmentally-responsive genes, suggesting variable roles for DNA methylation. In mammals, DNA methylation in different genomic contexts has different functions, and even within the same context may serve to: repress or up-regulate transcription, provide genomic stability or interact with other epigenetic modifications (Gutierrez-Arcelus *et al.*, 2013). Even though methylation levels are exceptionally low in some arthropod species, such as those studied here, the focus should not be on classifying a single function for DNA methylation in these species, such as the stability of housekeeping genes. Instead we should consider multiple context-dependent functions of DNA methylation.

This is also true for the function of imprinted genes, whilst parent-of-origin gene expression was identified for the first time in *B. terrestris* in this thesis, in a manner predicted by the kinship theory (Queller, 2003), multiple gene functions arose within the GO enrichment analysis. Imprinted genes currently characterised in mammals are

mostly involved in growth and behavioural traits, also supporting the kinship theory (Haig, 2000; Tycko and Morison, 2002). However, imprinting in mammals has still been found to affect a greater variety of biological pathways (Tycko and Morison, 2002), indicating other potential roles. As discussed below, in section 7.3.1, functional validation of individual imprinted or methylated genes will provide more accurate assessments of function.

Finally, variation in DNA methylation has been documented for the first time between genetically distinct *B. terrestris* colonies and between temporal sub-populations of *D. magna*. These findings shows the importance of accounting for genetic variation when attempting to assess differences in methylation profiles between non-isogenic individuals. Lea *et al.* (2017) highlight the importance of considering genetic relatedness in ecological methylation data sets. Associations of DNA methylation with, for example, a climate gradient, in a space-for-time study, may be confounded by genetic variation along the same transect (Lea *et al.*, 2017). Given the call for further research into the role of epigenetics within ecology and evolution the discovery of high methylation variation between replicates highlights the importance of considering genetic factors in future ecological epigenetic studies.

7.3 Future work

7.3.1 Functional validation

In order to understand the direct role of DNA methylation in any arthropod species, functional validation is needed. It is currently possible to alter genome-wide DNA methylation in arthropods via application of the chemical 5-aza-2'-deoxycytidine (Amarasinghe *et al.*, 2014; Cook *et al.*, 2019). This chemical irreversibly binds to DNMT enzymes which are responsible for DNA methylation maintenance (Christman, 2002). Whilst this causes a general loss in DNA methylation over time, not all loci are affected (Cook *et al.*, 2019). Additionally, modifying DNA methylation globally may provide some clues to function, e.g. *B. terrestris* workers were more likely to become reproduc-

tive after treatment (Amarasinghe *et al.*, 2014). However, this method does not assess the direct function of DNA methylation on a gene level.

More recently the CRISPR-Cas9 technology has been modified to allow the methylation or de-methylation of specific sites (Vojta *et al.*, 2016). This has currently been trialled *in vitro* in mammalian cells and *in vivo* in mice, where a Dnmt3a enzyme (involved in methylation establishment) or a Tet1 enzyme (involved in methylation removal) have been used to change methylation at specific sites within the genome (Liu *et al.*, 2016). CRISPR technology has already been successful in a number of insect species, including: *Drosophila melanogaster* (Bassett and Liu, 2014), *Tribolium castaneum* (Gilles *et al.*, 2015), *Bombyx mori* (Liu *et al.*, 2014), *Nasonia vitripennis* (Li *et al.*, 2017) and *Apis mellifera* (Kohno *et al.*, 2016). The application of CRISPR-Cas9 to modify DNA methylation on a per gene basis in arthropods would allow direct phenotypic responses to be observed, providing considerable insight into the function of DNA methylation in individual species on a gene level.

Modifying specific CpG sites would also allow for a greater mechanistic understanding of the cellular pathways potentially influenced by DNA methylation. As discussed throughout this thesis, histone modifications and chromatin arrangement may interact with DNA methylation to provide a phenotype. Utilising techniques such as ChIP-Seq (chromatin immunoprecipitation sequencing) and ATAC-Seq (assay for transposase-accessible chromatin sequencing), alongside RNA-Seq, would allow the molecular affects of changes in DNA methylation to be observed. ChIP-Seq involves using immunoprecipitation to enrich for DNA fragments associated with particular histone modifications (Blecher-Gonen *et al.*, 2013). However, this technique can be costly when multiple histone modifications are targets of interest. ATAC-Seq provides a more general assessment of the chromatin structure, sequencing adapters are ligated into any open chromatin regions allowing sequencing of only accessible DNA (Buenrostro *et al.*, 2015). Combining various epigenomic data sets with RNA-Seq from the same individuals would allow for a greater understanding of the epigenomic pathways which contribute to phenotype.

7.3.2 Genomic imprinting as a mechanism of plasticity

Radford *et al.* (2011) have proposed imprinted genes could act as a mechanism of plasticity by regulating gene expression in response to environmental change. Some imprinted genes have been shown to exhibit monoallelic expression (expression of a single allele) in only some tissue types and during only specific developmental phases (Charalambous *et al.*, 2003), showing the plastic potential of imprinted genes. Additionally, Matsuura *et al.* (2018) propose imprinted genes play a role in caste-determination in termites based on the influence of parental phenotypes on offspring caste-fate. The identification of parent-of-origin expression differences under differing experimental conditions would allow the role of imprinted genes in plasticity to be further understood. Ideally this work would use isogenic lines in order to minimise the effects of genotype.

Additionally, in order to assess the effects of genotype more thoroughly in the data generated in Chapter 5 (parent-of-origin methylation in *B. terrestris*), an improved experiment is recommended. The presence of cytosine SNPs may influence the methylation status of a given CpG (Wedd *et al.*, 2016), these SNPs cannot be easily or confidently identified in bisulfite treated DNA as cytosines are converted to thymine during the process (Liu *et al.*, 2012). To improve on the design of Chapter 5, whole genome sequencing of the parents may be carried out to identify a full complement of SNPs, this would allow for more confident identification of alleles in the offspring and allow the relationship of methylation and genotype to be determined.

7.3.3 Transgenerational epigenetic adaptation

In order to understand the role of DNA methylation in arthropod adaptation it is important to understand the developmental processes underlying DNA methylation heritability. In mammals DNA methylation is almost entirely wiped and re-established during development (Messerschmidt *et al.*, 2014). Drewell *et al.* (2014) examined genome-wide methylation differences between *A. mellifera* eggs, males and sperm. They found reduced levels of DNA methylation in adult males compared to both eggs and sperm and higher levels of methylation in eggs compared to sperm. Additionally, Kay *et al.*

(2018) found higher expression levels of *Dnmt3* in embryos of the ant, *Solenopsis invicta*, compared to instar developmental stages and adults. These results combined suggest DNA methylation likely undergoes a dynamic fluctuation during development in hymenoptera, as seen in mammals. However, given the identification of parent-of-origin methylated CpGs in Chapter 5, a small number of sites may also escape global erasure, as also observed in mammals. Considering the diverse methylation profiles of species within the Arthropoda phylum, differences in genome-wide methylation, in more developmental stages, as well as gametes, are needed for many other species in order to further clarify this process.

The direct heritability of DNA methylation may only be limited to a small number of sites in some species. However, DNA methylation linked to the underlying genomic code provides a means of direct transmission of many epigenetic marks between generations. Chapter 6 in this thesis begins to explore a data set which may shed light on the heritability of DNA methylation in a crustacean species and may also help determine how much of the methylome is linked to genotype. I plan to expand on the analysis done in Chapter 6 by identifying different SNP positions between genotypes, using previously generated whole-genome data. I will then be able to carry out a quantitative trait locus analysis, integrating previously generated RNA-seq from the same genotypes. This type of analysis has previously been carried out by Lu *et al.* (2019), they identified associations between SNPs, DNA methylation and gene expression in human blood cells. Further exploring the relationship between genotype, epigenotype and phenotype will allow greater understanding of the function of DNA methylation across arthropod species.

Additionally, the nature of the data produced from whole-genome bisulfite sequencing lends itself to population genetic analyses. As individual genomic positions may be methylated or unmethylated they can be treated as single methylation polymorphisms (SMPs). Geoghegan and Spencer (2012) have adapted traditional population genetic models to allow for epigenetic considerations. The application of these models to population epigenomic data, as generated in Chapter 6, may allow new insights into the direct effects of selection on epigenetic loci. These examples highlight how the application of techniques and methods from various other disciplines and fields may help

progress ecological epigenetic research.

7.4 Conclusions

The work in this thesis has made various new contributions to the field of ecological epigenetics. Briefly I have: characterised caste-specific bumblebee methylomes, identifying no direct causal relationship with caste-determination via the regulation of gene expression. This highlights the importance of understanding the full molecular pathways involved in phenotype production. I have identified parent-of-origin gene expression in *B. terrestris*, which provides support for the kinship theory of genomic imprinting and contributes the first genome-wide evidence of imprinted genes in this species. Parent-of-origin methylation was also identified in a small number of genes, indicating imprinted genes in insects may be regulated by a different process, compared to mammals. Allele-specific methylation throughout has not been associated with allele-specific gene expression, additionally indicating a potential role for other epigenetic marks in the process of generating allele-specific expression / imprinted genes. Using *D. magna* I have identified temporal DNA methylation fluctuations in a single population, potentially in response to environmental stress. This provides the first evidence for DNA methylation changes through evolutionary time in a single population. With the application of analyses from other research fields these data may aid our understanding of the adaptive potential of DNA methylation. Overall the results of this thesis highlight the need for functional validation within the field of ecological epigenetics, along with improved bioinformatic pipelines which consider the impact of genotype on DNA methylation.

Phenotypic plasticity is the production of multiple phenotypes from a single genome and is notably observed in social insects. Multiple epigenetic mechanisms have been associated with social insect plasticity, with DNA methylation being explored to the greatest extent. DNA methylation is thought to play a role in caste determination in *Apis mellifera*, and other social insects, but there is limited knowledge on its role in other bee species. In this study, we analyzed whole genome bisulfite sequencing and RNA-seq data sets from head tissue of reproductive and sterile castes of the eusocial bumblebee *Bombus terrestris*. We found that genome-wide methylation in *B. terrestris* is similar to other holometabolous insects and does not differ between reproductive castes. We did, however, find differentially methylated genes between castes, which are enriched for multiple biological processes including reproduction. However, we found no relationship between differential methylation and differential gene expression or differential exon usage between castes. Our results also indicate high intercolony variation in methylation. These findings suggest that methylation is associated with caste differences but may serve an alternate function, other than direct caste determination in this species. This study provides the first insights into the nature of a bumblebee caste-specific methylome as well as its interaction with gene expression and caste-specific alternative splicing, providing greater understanding of the role of methylation in phenotypic plasticity within social bee species. Future experimental work is needed to determine the function of methylation and other epigenetic mechanisms in insects.

KEY WORDS: Bombus, bumblebee, expression, hymenoptera, methylation.

Impact Summary

Social insects, such as ants, termites, bees, and wasps, can produce individuals with extreme physical and behavioral differences within the same colony known as castes (e.g., workers/soldiers/queens). These individuals have similar genomes and many studies have associated epigenetic mechanisms with the differences observed. Epigenetic modifications are changes that affect how genes are expressed without changing the underlying DNA code. Here, we investigated differences in DNA methylation (a well-researched modified base) between

different reproductive castes of the bumblebee, *Bombus terrestris*, an economically and environmentally important pollinator species. We found that *B. terrestris* has a similar methylation profile to other holometabolous insect species in terms of the distribution of methylation throughout the genome and the relationship between methylation and gene expression. Genes that have differences in methylation between reproductive castes are involved in multiple biological processes, including reproduction, suggesting methylation may hold multiple functions in this species. These differentially methylated genes are also different to differentially methylated

genes identified between honeybee reproductive castes, again suggesting methylation may have a variable function. These findings provide a greater understanding of the role of methylation in caste determination in social insect species.

Phenotypic plasticity is the production of multiple phenotypes from a single genome. It plays a crucial role in the adaptive capabilities of species (Chevin et al. 2010) and is notably observed in social insects. Social insects exhibit sometimes extreme morphological and behavioral differences within a single colony, known as castes. The mechanisms by which species develop differences between castes are diverse; some species use only environmental cues, whereas others rely only on inherited changes, with many species falling somewhere in between these two extremes (Matsuura et al. 2018). For example, some ant species from the *Pogonomyrmex* genus have purely genetic caste determination (Mott et al. 2015). On the other hand, many ant species undergo caste determination in response to only the environment, indicating their genomes must contain the code for all caste possibilities, with the phenotype potentially determined by epigenetic factors (Bonasio et al. 2012).

Multiple epigenetic mechanisms have been associated with social insect plasticity. Histone modifications have been shown to be involved with plasticity, for example changes in histone acetylation alter the behavior of major workers of the ant species *Camponotus floridanus*, making them more similar to the behavior of minor workers (Simola et al. 2016). Variation in microRNA expression levels has been identified in both honeybee (Ashby et al. 2016) and bumblebee (Collins et al. 2017) castes. However, the most active research in this area has been focused on DNA methylation (Glastad et al. 2015).

DNA methylation is the addition of a methyl group to a cytosine nucleotide. In mammals, methylation primarily occurs in a CpG context (CpG referring to a cytosine base immediately followed by a guanine base); the percentage of CpGs methylated is usually over 70%, with methylation serving to repress gene expression when occurring in promoter regions (Feng et al. 2010). However, in insects, it is generally found in much lower quantities, ranging from zero methylation in most Diptera species studied to >2% in Hymenoptera and up to 14% in some species of Blattodea (Provataris et al. 2018). It is also enriched in gene bodies rather than throughout the genome, as in mammals (Fang et al. 2012; Wang et al. 2013), with a possible role in alternative splicing (Bonasio et al. 2012).

DNA methylation has been associated with the switching of worker castes in honeybees (Herb et al. 2012). A major finding

was that silencing of the *Dnmt3* gene (involved in methylation establishment) in larvae produced queens rather than workers (Kucharski et al. 2008). DNA methylation has also been linked with alternative splicing differences between castes in two ant species (Bonasio et al. 2012) and is thought to be involved in caste determination in *Copidosoma koehleri*, a species of primitively social wasp (Shaham et al. 2016). However, it is clear DNA methylation is not a conserved mechanism in Hymenoptera for caste differentiation. No association between caste and methylation has been found in a number of wasp and ant species (Patalano et al. 2015; Standage et al. 2016). Additionally, the statistical methods of previous next generation sequencing analyses on social insect methylation have been brought into question (Libbrecht et al. 2016).

A greater variety of species are needed to begin to understand the role of DNA methylation in social insect caste determination. Here, we assess whole genome methylation differences between reproductive castes of the bumblebee, *Bombus terrestris*, with an aim to investigate the role of methylation in caste determination in this species. Bumblebees are primitively eusocial and are an important pollinator species, both economically and environmentally. They are generalist pollinators and are keystone species in some ecosystems (Woodard et al. 2015). *Bombus terrestris* colonies are annual and are founded by a singly mated queen in early spring; she will lay diploid eggs resulting in female workers and later switch to male haploid eggs, known as the switching point (Bloch 1999). A competition phase then occurs between queens and workers, where some workers will become reproductive and produce their own haploid sons (Alaux et al. 2006); this results in distinct reproductive worker castes within the colony. Multiple recent studies have highlighted *B. terrestris* as an ideal organism to assess methylation as a potential regulatory mechanism for reproductive caste determination (Amarasinghe et al. 2014; Lonsdale et al. 2017; Li et al. 2018).

Methylation regulatory genes were identified in the bumblebee genome and have since been shown to have varying expression levels between queens, workers and drones (Li et al. 2018). Additionally, genes showing allele-specific methylation and gene expression have been identified and are enriched in reproductive-related processes (Lonsdale et al. 2017). Finally, experimental changes in methylation in *B. terrestris* workers has been shown to alter levels of reproductive behavior (Amarasinghe et al. 2014). Although these studies highlight differences in methylation between *B. terrestris* castes, it is still unclear where those differences are within the genome and also whether methylation differences are related to changes in gene expression, potentially leading to caste differentiation.

In this study, we compared whole genome bisulfite sequencing (WGBS) data sets from reproductive and sterile worker castes of *B. terrestris*, allowing us to identify differences in methylation

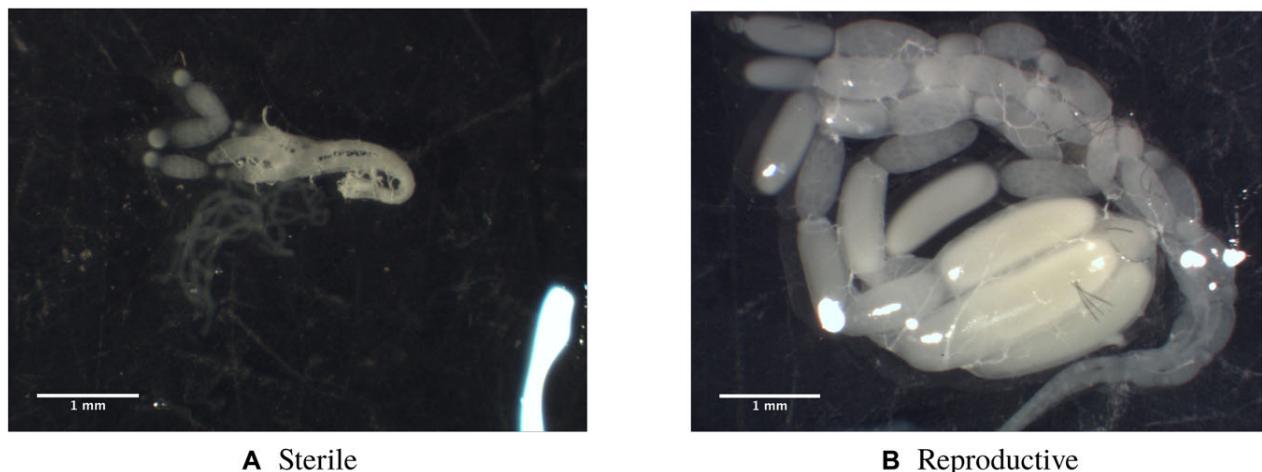

Figure 1. (A) one half of a pair of ovaries from a sterile bumblebee worker, with a score of 0. (B) One half of a pair of ovaries from a reproductive bumblebee worker, with a score of 4. Scores generated following Duchateau and Velthuis (1988).

at base-pair resolution throughout the genome. We then linked these data with gene expression data for the same individuals to identify a potential relationship between gene expression and methylation regarding reproductive caste determination. Within this study, we have also characterized the *B. terrestris* methylome to allow comparative analyses between castes. If methylation plays a role in caste determination, we would expect to find differentially methylated genes between castes, with functions related to reproduction. We would also expect any differentially methylated genes between castes to be enriched for differentially expressed genes or genes which have different exon usage between castes. Additionally, if there is a conserved role for methylation in caste determination in Hymenoptera, we would expect to find orthologous genes differentially methylated between *B. terrestris* reproductive castes and *Apis mellifera* reproductive castes.

Methods

BEE HUSBANDRY AND TISSUE SAMPLING

Three *B. terrestris* colonies, from Agralan, UK, were reared in constant red light at 26°C and 60% humidity. They were fed 50% v/v apriary solution (Meliose-Roquette, France) and pollen (Percie du set, France) ad libitum. Callow workers, less than 24 hours old, were taken from each colony and placed in small rearing boxes of five individuals.

The worker bees were sacrificed at six days old. For each bee, the head was snap frozen in liquid nitrogen. Through dissection in 1% PBS solution, the reproductive status of each bee was determined and classed as either reproductive, sterile, or intermediate. Workers were classed as having developed ovaries, and therefore reproductive, if the largest oocyte was larger than the trophocyte follicle (Duchateau and Velthuis 1988). This measurement

is tightly correlated with reproductive status (Foster et al. 2004; Geva et al. 2005). The ovaries of each worker were weighed, and the length of the largest oocyte was measured using ImageJ version 1.50e (Schneider et al. 2012) (Supporting Information 1.0.0). Worker “reproductiveness” was classified on a scale from 0 to 4 based on Duchateau and Velthuis (1988), 0 being completely sterile (Fig. 1A) and 4 having fully developed ovaries (Fig. 1B).

RNA AND DNA EXTRACTION AND SEQUENCING

Three reproductive individuals and three sterile individuals from each of the three colonies were selected for RNA and DNA extraction (see Fig. 2 for an overview). Heads were cut in half (using a lateral incision central between the eyes). Each head half was randomly allocated for either DNA/RNA extraction to avoid left/right hemisphere bias. RNA was extracted using the Sigma-Aldrich GenElute Mammalian Total RNA Miniprep kit and DNA was extracted using the Qiagen DNeasy blood and Tissue kit, individually for each half head per sample, following manufacturers protocols. The extracted RNA was treated with DNase and the extracted DNA was treated with RNase. DNA was pooled per colony and reproductive status, that is, the three reproductive samples from a single colony were pooled to create one representative reproductive sample for that colony (Fig. 2). RNA samples were processed individually. DNA and RNA quality and quantity were determined by Nanodrop and Qubit® fluorometers (Supporting Information 1.0.1 and 1.0.2). A total of 18 RNA samples (three individuals per reproductive status for each of the three colonies) were sent for 100 bp paired-end sequencing and six pooled DNA samples (one sample per reproductive status per colony consisting of three individuals per pool) were sent for 100 bp paired-end bisulfite sequencing on a HiSeq 2000 machine (Illumina, Inc.) by BGI Tech Solution Co., Ltd. (Hong Kong). Library preparation

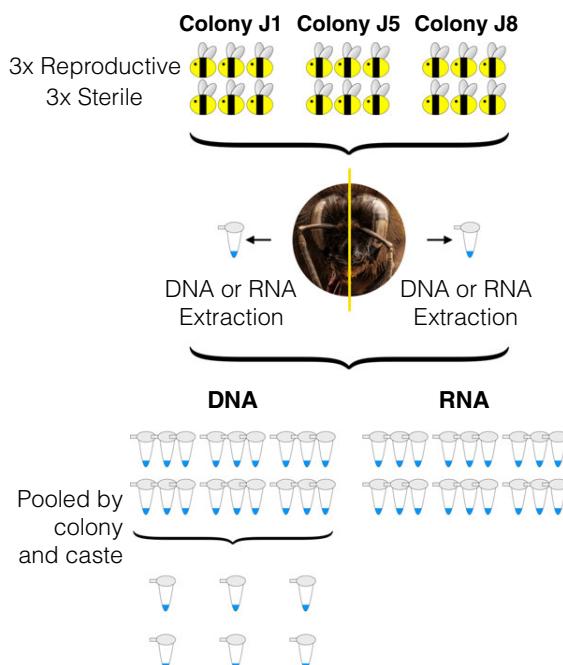

Figure 2. Overview of sample preparation for sequencing. Three reproductive workers and three sterile workers were selected from three colonies (J1, J5 and J8 represent colony names). Half of each head was randomly allocated for RNA/DNA extraction. All 18 RNA samples were sent for RNA-Seq (three of each caste from each colony). DNA samples were pooled by colony and caste creating a representative reproductive and sterile sample per colony.

was carried out by BGI using their standard directional WGBS pipeline. A 1% lambda spike was included as an unmethylated control in each WGBS library.

DIFFERENTIAL EXPRESSION AND ALTERNATIVE SPLICING

Low-quality bases were removed from the RNA-Seq libraries using CutAdapt version 1.1 (Martin 2011). Reads were aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1; Sadd et al. 2015) using STAR version 2.5.2 (Dobin et al. 2016) with standard parameters. Reads were counted per gene using HTseq version 0.10.0 (Anders et al. 2015). A differential expression analysis was then carried out after count normalization via a negative binomial generalized linear model (GLM) implemented by DEseq2 version 1.20.0 (Love et al. 2014) in R version 3.4.0 (<http://www.R-project.org>) with colony and reproductive status as independent variables. Genes were classed as differentially expressed when $q < 0.05$ after correction for multiple testing using the Benjamini–Hochberg method (Benjamini and Hochberg 1995).

Differential exon expression was determined using the DEXseq version 1.26.0 R package (Anders et al. 2012); briefly

this package calculated the ratio of expression of a given exon in a given gene relative to other exons in the same gene for each sample. The relative exon expression per colony was then calculated taking into account dispersion between colonies. A GLM was then used to test for a difference in the relative proportion of expression of each exon between castes, accounting for sample differences and overall gene expression differences between castes; P -values were corrected for multiple testing using the Benjamini–Hochberg method (Benjamini and Hochberg 1995) and exons were classed as differentially used between castes when $q < 0.1$. The benefit of this method over general alternative splicing analysis is that specific differentially used exons can be identified between castes allowing the relationship with exonic methylation to be investigated.

DIFFERENTIAL METHYLATION

BS-seq libraries were aligned to the reference genome (Bter_1.0, Refseq accession no. GCF_000214255.1; Sadd et al. 2015) using Bismark version 0.16.1 (Krueger and Andrews 2011) and bowtie2 version 2.2.6 (Langmead and Salzberg 2012) with standard parameters. Bismark was also used to extract methylation counts and carry out deduplication. Annotation of the methylation counts with genomic features (from the *B. terrestris* annotation file, Refseq accession no. GCF_000214255.1) was carried out using custom R scripts implementing the sqldf version 0.4.11 library (Grothendieck 2017). Bisulfite conversion efficiency was calculated by aligning reads to the lambda reference genome (Refseq accession no. GCF_000840245.1) and calculating the single-site methylation level, as in Schultz et al. (2012).

Prior to differential methylation analysis, coverage outliers (above the 99.9th percentile) were removed along with bases covered by less than 10 reads. The methylation status of each CpG was then determined using the “methylation status calling” (MSC) procedure, as described in Cheng and Zhu (2014). Briefly, this involves applying a mixed binomial model to each CpG, which includes estimation of both the false discovery rate (FDR) and the non-false discovery rate to make a binary methylation call per site. CpG sites were then filtered to remove any site that did not return as methylated in at least one sample. This functions to reduce the number of tests and hence decreases the required stringency of the later FDR correction applied during differential methylation testing. This is a vital step for species, such as bumblebees, with extremely low genome methylation where the majority of sites show zero methylation in all samples. A logistic regression model was then applied via the R package methylKit version 1.6.1 (Akalin et al. 2012) to determine differentially methylated sites, taking into account colony as a covariate due to high inter-colony variation (see Supporting Information 2.0). A minimum difference of at least 10% methylation and a q -value of <0.05 were required for a single site to be classed as differentially

methylated. Genes containing at least one differentially methylated CpG and a minimum weighted methylation difference (Schultz et al. 2012) of 10% across the entire gene were classed as differentially methylated between reproductive castes.

We chose not to include a permutation test as part of the differential methylation analysis, as has been seen in previous research (Libbrecht et al. 2016; Arsenault et al. 2018), although it is included in our Supporting Information data. There is structure present in our data due to high methylation variation between colony replicates. When structure is present within data, permutation tests do not produce reliable outcomes, as discussed in Winkler et al. (2015). A higher number of replicates would allow label shuffling within confounding factors, maintaining the structure of the data, thus allowing a valid permutation test (see Supporting Information 2.0).

GENE ONTOLOGY ANALYSIS

Gene ontology (GO) terms for *B. terrestris* were taken from a custom database made in Bebane et al. (2019). GO enrichment analysis was carried out using a hypergeometric test with Benjamini–Hochberg multiple-testing correction (Benjamini and Hochberg 1995). GO terms were defined as enriched when $q < 0.05$. GO terms from differentially methylated genes were tested for enrichment against GO terms associated with all methylated genes. Genes were classed as methylated when the weighted methylation score per gene was greater than zero (Schultz et al. 2012). Additionally, the GO terms associated with hypermethylated genes in either sterile or reproductive workers were tested for enrichment against the GO terms associated with all differentially methylated genes between castes to determine if there are different functions for hypermethylated genes in either sterile or reproductive workers. GO terms for differentially expressed genes and genes containing different exon usage between castes were tested for enrichment against GO terms associated with all genes identified in the RNA-seq data. REVIGO (Supek et al. 2011) was used to obtain the GO descriptions from the GO identification numbers.

COMPARATIVE ANALYSES

The hypergeometric test was applied to gene lists from the various analyses to determine if any overlaps were statistically significant. Custom R scripts were used to investigate the relationship between gene expression and methylation. A reciprocal blast between the honeybee (Amel_4.5, Refseq accession no. GCA_000002195.1) and bumblebee genome (Bter_1.0, Refseq accession no. GCA_000214255.1) was carried out using blast+ version 2.5.0 (Camacho et al. 2009), where the fasta sequence for each gene of each species was blasted against a custom database containing the fasta sequence for every gene of the opposite species, allowing only one match per gene and a minimum e -value of 1×10^{-3} . Gene matches were then filtered to ensure

only matches that occurred in both directions and to the same gene were kept. For example, multiple honeybee genes matched the same bumblebee gene, therefore all of these matches were discarded. This allowed us to construct a database of putative orthologous genes. A custom script was then used to check for overlap between the differentially methylated genes identified here and differentially methylated genes identified in Lyko et al. (2010) between honeybee reproductive castes.

Results

GENOME-WIDE METHYLATION DIFFERENCES BETWEEN CASTES

Up to a maximum of 10 bp were trimmed from the start of all reads due to base bias generated by the Illumina sequencing protocol (Krueger et al. 2011). The mean mapping efficiency was $63.6 \pm 1.4\%$ (mean \pm SD) and the mean coverage was 17.7 ± 0.5 reads per base; the average number of uniquely mapped reads was $27,709,214 \pm 753,203$. The mean bisulfite conversion efficiency, calculated from the unmethylated lambda spike, was $99.55 \pm 0.02\%$. After accounting for the conversion efficiency, there were no methylated cytosines in a non-CpG context. The mean single site methylation level (Schultz et al. 2012) in a CpG context was determined as $0.22 \pm 0.07\%$, calculated from the number of methylated cytosines divided by the sum of methylated and unmethylated cytosines and accounting for bisulfite conversion efficiency.

A total of 3412 genes were classed as methylated, that is, they had a weighted methylation level >0 in at least one sample. There was no significant difference in the overall weighted methylation level of the methylated genes between reproductive and sterile workers (Mann–Whitney U test: $W = 5,948,300$, $P = 0.1172$, Fig. 3A). GO terms enriched in methylated genes compared to all genes annotated in the genome ($q < 0.05$) include a large variety of biological processes (Supporting Information 1.0.5). Specifically, *posttranscriptional regulation of gene expression* (GO:0010608) and *histone modification* (GO:0016570) are enriched as well as terms related to reproductive processes, for example, *reproduction* (GO:0000003) and *oogenesis* (GO:0048477).

There was no significant difference in the weighted methylation level of all genomic features between reproductive and sterile workers (two-way analysis of variance [ANOVA], interaction between genomic feature and reproductive status; $F_{1,6} = 0.637$, $P = 0.701$, Fig. 3B), we also tested for differences in methylation levels of putative promoters but as promoter regions are currently unannotated for the current genomic annotation we feel these results are not reliable (Supporting Information 2.1, Fig. S3a). Irrespective of worker reproductive status, we found methylation differences between genomic features (Kruskal–Wallis; chi-squared = 729.35, $df = 7$, $P < 2.2 \times 10^{-16}$), with methylation being

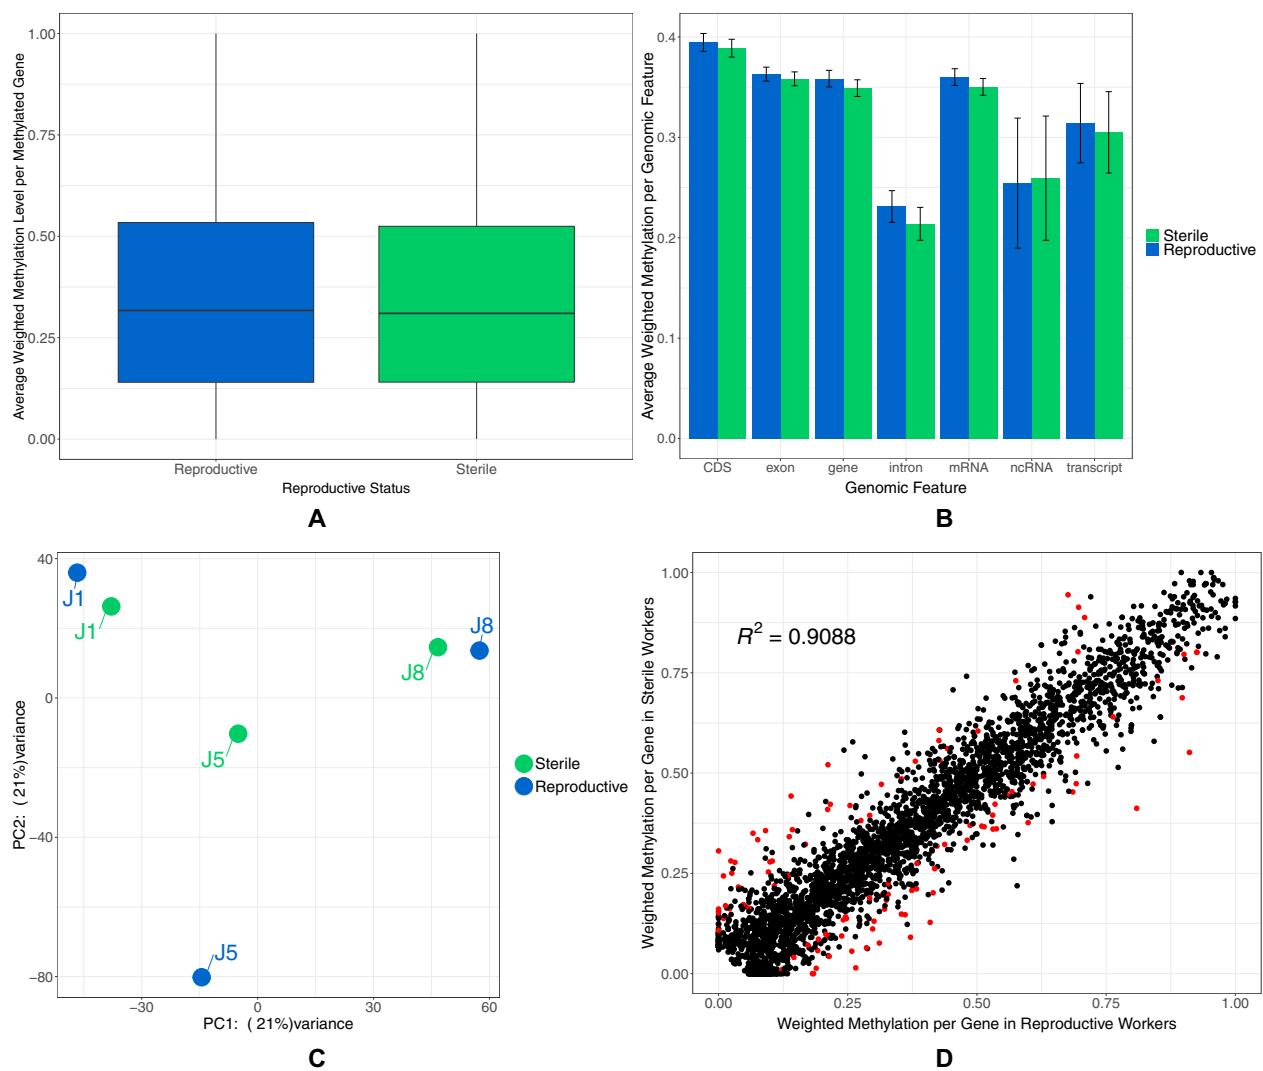

Figure 3. (A) Box plot of the mean weighted methylation level of methylated genes ($n = 3412$) across colonies for each caste. (B) The mean weighted methylation level across colonies for each genomic feature for both reproductive and sterile workers. Error bars are 95% confidence intervals of the mean. (C) PCA plot generated by methylKit showing samples cluster by colony using per site CpG methylation. (D) Scatter plot of the average weighted methylation level (across colonies) for reproductive workers against sterile workers. Each dot represents a gene and each red dot represents a differentially methylated gene ($q < 0.05$ and a minimum gene weighted methylation difference of 10%).

significantly enriched in coding regions compared to introns and ncRNAs (Supporting Information 1.0.6).

We also found no difference in the weighted methylation level across the genome per linkage group between reproductive and sterile workers (two-way ANOVA, interaction between linkage group and reproductive status; $F_{1,17} = 0.034$, $P = 1.0$, Supporting Information 2.1, Fig. S3b). Weighted methylation did vary significantly between linkage groups within the genome irrespective of reproductive status (Kruskal–Wallis chi-squared = 131.59, $df = 17$, $P < 2.2 \times 10^{-16}$, Supporting Information 1.0.6), however due to the number of unplaced scaffolds these results should be interpreted with care.

Finally, using CpG methylation levels, samples cluster by colony rather than by reproductive caste (Fig. 3C). This indicates high intercolony variation in methylation.

GENE LEVEL METHYLATION DIFFERENCES BETWEEN CASTES

A total of 4,681,131 CpG sites had a coverage > 10 in all six sample data sets, of those 16,194 returned as methylated in at least one sample after running the MSC procedure. A total of 624 of these CpGs were identified as differentially methylated between reproductive castes, 613 of these were located in a total of 478 genes (Supporting Information 1.0.4). Note that 11 differentially

methylated CpGs were located outside of genes, nine of those were within 5000 bp upstream or downstream of a gene with no apparent trend in the expression of near-by genes (Supporting Information 1.0.5). 111 genes contained a differentially methylated CpG and also had a weighted methylation difference of 10% between reproductive and sterile workers (Supporting Information 1.0.7, Fig. 3D).

Of the 111 differentially methylated genes, there was no preference for genes to be hypermethylated in either reproductive or sterile workers (chi-squared goodness of fit, $X^2 = 2.027$, $df = 1$, $P = 0.1545$), with 63 genes hypermethylated in reproductive workers and 48 genes hypermethylated in sterile workers.

GO terms enriched in differentially methylated genes compared to all methylated genes ($q < 0.05$) contained a variety of biological processes (Supporting Information 1.0.8), among these processes were terms involved with reproduction, including *meiotic cell cycle* (GO:0051321) and *female germline ring canal stabilization* (GO:0008335). One of the genes associated with the above GO terms is *eggless* (LOC100647514), which shows hypermethylation in sterile workers. This gene contains a Methyl-CpG binding domain, which has been associated with histone H3, lysine 9-specific methyltransferase that contributes to repression of transcription (Wakefield et al. 1999).

There were no specific GO terms enriched for either the hypermethylated genes in sterile workers or the hypermethylated genes in reproductive workers compared to all differentially methylated genes as a background.

EXPRESSION DIFFERENCES BETWEEN CASTES

All reads had 13 bp trimmed from the start due to base bias generated by the Illumina protocol (Krueger et al. 2011). The mean percentage of uniquely mapped reads was $89.4 \pm 0.8\%$ (mean \pm SD). This equated to a mean of $10,115,366 \pm 1,849,600$ uniquely mapped reads. After running a differential expression analysis with DESeq2, the decision was made to remove one sample from all downstream analysis due to possible mislabeling of reproductive status (Supporting Information 2.2).

Samples cluster by reproductive status when the expression of all genes is assessed (Fig. 4A). A total of 334 genes were identified as differentially expressed ($q < 0.05$, Fig. 4B). There was no difference in the number of upregulated genes in either reproductive or sterile workers (chi-squared goodness of fit: $X^2 = 0.2994$, $df = 1$, $P = 0.5843$), with 172 genes upregulated in reproductive workers and 162 genes upregulated in sterile workers.

One of the most upregulated genes in reproductive workers was vitellogenin (gene ID: LOC100650436, log₂ fold-change of 2.92, $q = 4.85 \times 10^{-6}$). Previous work has found upregulation of this gene in reproductive *B. terrestris* workers is linked to aggressive behavior rather than directly to ovary development (Amsalem et al. 2014). Additionally, two genes coding for serine-

protease inhibitors were found to be upregulated in reproductive workers; these proteins have been linked to reproduction in other insect species (Bao et al. 2014).

Enriched GO terms associated with the differentially expressed genes compared to the background of all genes in the RNA-seq data ($q < 0.05$) contained a variety of biological processes, including reproductive-related terms (Supporting Information 1.1.0). Additionally, there were no specific GO terms enriched in upregulated genes of reproductive workers compared to all differentially expressed genes as the background. However, there were two GO terms enriched for upregulated genes in sterile workers compared to differentially expressed genes as the background, these were as follows: *cellular lipid metabolic process* (GO:0044255) and *isoprenoid biosynthetic process* (GO:0008299).

A total of 59 genes were identified as having differential exon usage, containing 83 differentially expressed exons between reproductive castes ($q < 0.1$, Supporting Information 1.1.1, see example Fig. 4C). There is no difference in the number of upregulated exons in reproductive workers compared to sterile workers (chi-squared goodness of fit: $X^2 = 3.4819$, $df = 1$, $P = 0.06204$), with reproductive workers having 33 upregulated exons and sterile workers having 50 upregulated exons. The enriched GO terms associated with genes containing differentially used exons compared to the background of all genes in the RNA-seq data ($q < 0.05$) contained a variety of biological processes (Supporting Information 1.1.2), however there were no GO terms with a clear connection to reproductive processes.

RELATIONSHIP OF METHYLATION AND GENE EXPRESSION

On an individual gene basis, methylation and reproductive caste have no effect on expression level (Fig. 5A and 5B, linear mixed effects model with colony as a random factor; methylation: $df = 49172$, $t = -1.295$, $P = 0.195$, reproductive status: $df = 49172$, $t = -0.638$, $P = 0.524$, interaction between methylation and reproductive status: $df = 49172$, $t = 0.112$, $P = 0.911$).

However, gene groups with varying methylation levels show different levels of expression (Kruskal–Wallis; chi-squared = 131.59, $df = 17$, $P < 2.2 \times 10^{-16}$; Fig. 5C). Specifically genes with no methylation show higher expression than genes classed as lowly methylated but lower expression than genes classed as medium/high in terms of methylation (Dunn's test with Benjamini–Hochberg multiple-testing correction; no methylation vs. low methylation: $Z = -13.14$, $P = 4.09 \times 10^{-39}$, no methylation vs. medium methylation: $Z = 4.5$, $P = 6.82 \times 10^{-6}$, no methylation vs. high methylation: $Z = 7.32$, $P = 3.86 \times 10^{-13}$; Fig. 5C). Reproductive caste still has no effect on gene expression in relation to methylation status when genes are grouped

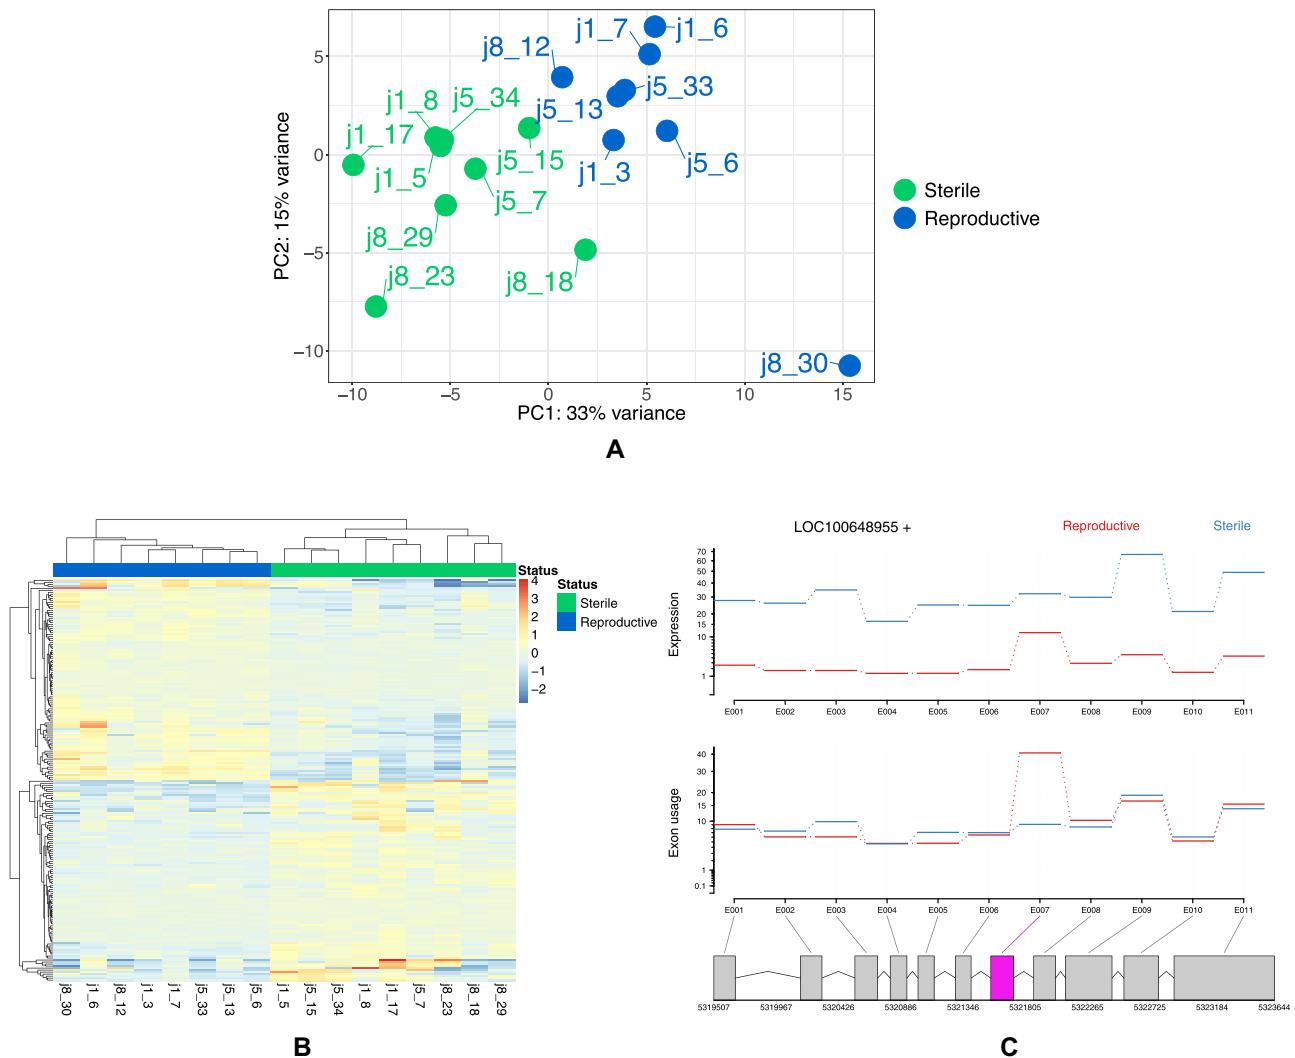

Figure 4. (A) PCA plot showing samples cluster by caste for gene expression, the first half of each label represents the colony name and the second half is the individual identification number. (B) Heatmap showing the 100 top differentially expressed genes between reproductive castes, samples cluster by reproductive status. Sample names are shown at the bottom of the plot. (C) An example of a gene that shows differential exon expression in one exon between reproductive castes. The top section of the plot shows the general expression differences between castes, the second section shows the normalized counts per exon (given expression differences) and the third section highlights the differentially expressed exon in pink. Gene shown: *probable peroxisomal acyl-coenzyme A oxidase 1* (ID: LOC100648955).

(two-way ANOVA, interaction between reproductive status and methylation level; $F_{1,3} = 0.017, P = 0.99$).

A linear mixed effects model was then applied to assess the relationship between gene expression, methylation, and reproductive status for only methylated genes using colony as a random factor. There is a positive relationship between gene expression and methylation in methylated genes with reproductive status having no effect (Fig. 5D, methylation: $df = 17,390, t = 6.154, P = 7.72 \times 10^{-10}$, reproductive status: $df = 17,390, t = -0.328, P = 0.743$, interaction between methylation and reproductive status: $df = 17,390, t = -0.200, P = 0.842$).

RELATIONSHIP OF METHYLATION AND DIFFERENTIAL GENE EXPRESSION

Weighted methylation differences between differentially expressed genes and nondifferentially expressed genes were assessed along with weighted methylation differences between genes containing differentially expressed exons and genes without differentially expressed exons (Fig. 6A and 6B). Differentially expressed genes and genes containing differentially expressed exons between castes show lower methylation than nondifferentially expressed genes or genes containing no differentially expressed exons, with reproductive status and the interaction of

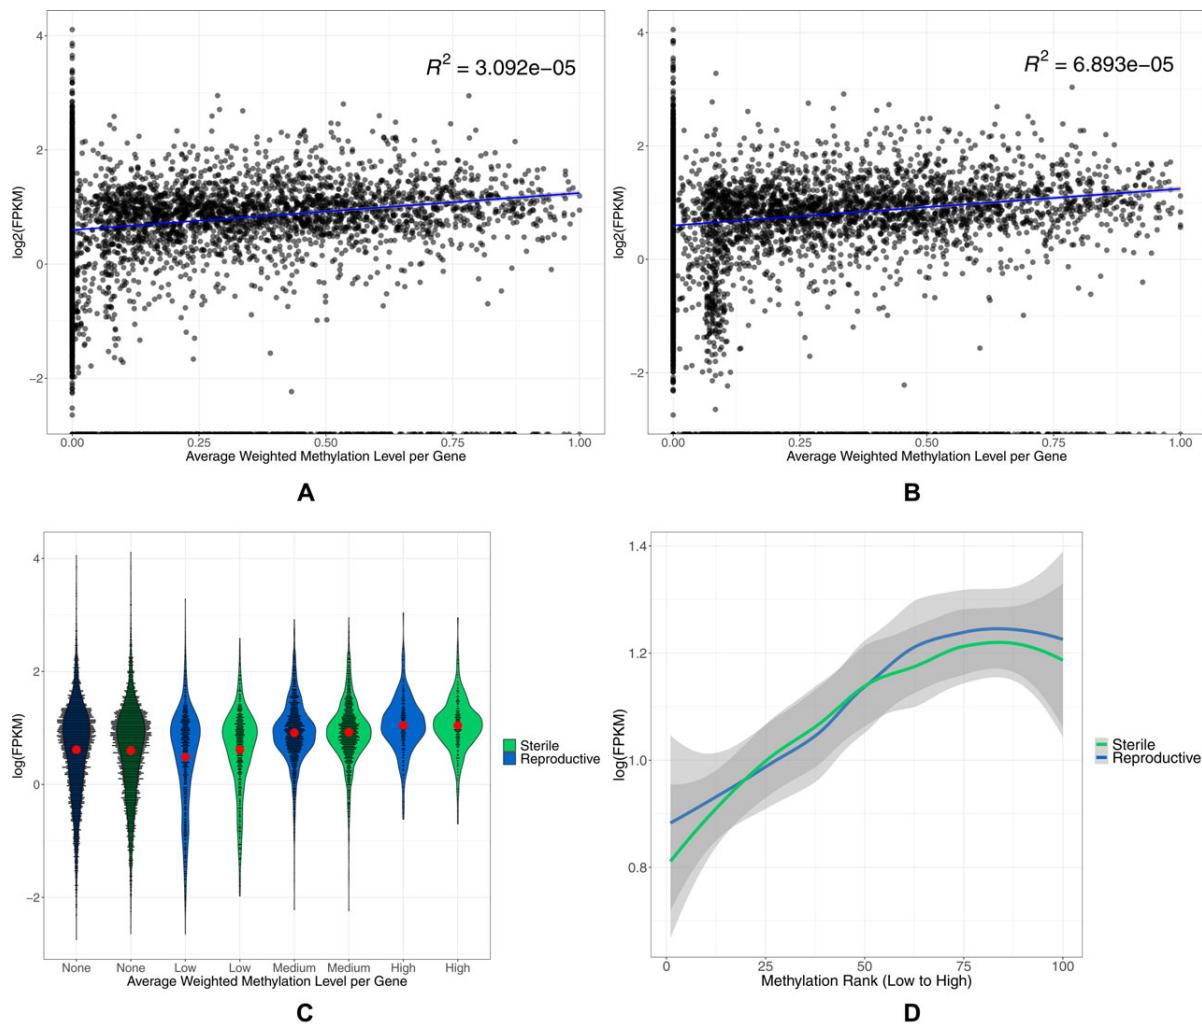

Figure 5. (A and B) The colony average weighted methylation level for every gene plotted against the $\log(\text{FPKM})$ of that gene for sterile workers and reproductive workers, respectively. Each black dot represents a single gene. The blue line is a fitted linear regression with the gray shaded area representing 95% confidence intervals. (C) Violin plots showing the distribution of the data via a mirrored density plot, meaning the widest part of the plots represent the most genes. Weighted methylation level per gene per caste, averaged across colonies, was binned into four categories, no methylation, low (>0 –0.2), medium (0.2–0.7), and high (0.7–1), as in Liu et al. (2019). The red dot indicates the mean with 95% confidence intervals. Each black dot represents a single gene. (D) Binned methylated genes ($n = 3412$, 100 being the most highly methylated) based on the mean weighted methylation level across colonies per reproductive caste, plotted against the $\log(\text{FPKM})$ expression level per gene. Data were smoothed using the LOESS method, and gray areas are 95% confidence intervals.

reproductive status with gene expression type having no effect (Table 1, Fig. 6A and 6B). When weighted methylation is assessed per exon, differentially expressed exons have lower weighted methylation than nondifferentially expressed exons (Fig. 6C), with reproductive status and the interaction of reproductive status and exon expression having no effect (Table 1).

Of the 334 differentially expressed genes, 50 also showed some level of weighted methylation difference between reproductive and sterile workers (weighted methylation difference >0) (Fig. 6D). However, there is no relationship between the

level of differential methylation and the level of differential expression for these 50 genes (linear model: $F_{1,58} = 0.2717$, $P = 0.6046$).

Gene lists were checked for potential overlap from all analyses. There was no significant overlap between differentially methylated genes and differentially expressed genes (two genes, hypergeometric test; $P = 0.658$, Fig. 7A). There was also no significant overlap between differentially methylated genes and genes containing differentially expressed exons (one gene, hypergeometric test; $P = 0.12$; Fig. 7A).

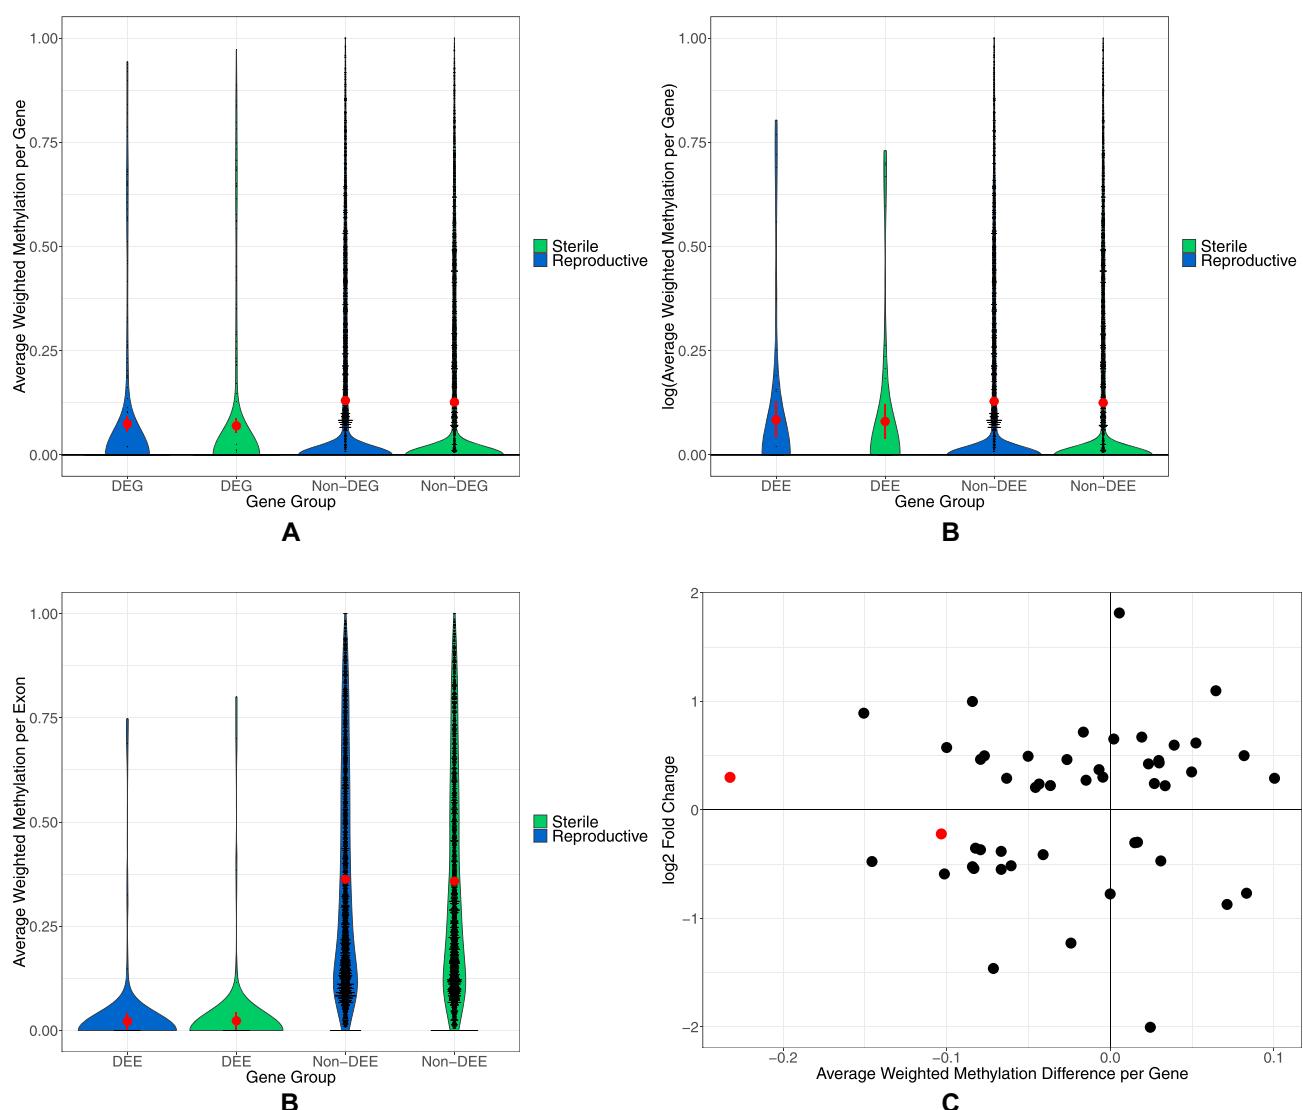

Figure 6. (A) Violin plots showing the distribution of the data via a mirrored density plot, meaning the widest part of the plots represent the most genes. The red dots represent the mean of each gene set along with error bars representing 95% confidence intervals of the mean. Each black dot is an individual gene. The mean weighted methylation per gene across colonies per caste is plotted for either differentially expressed genes (DEG) or nondifferentially expressed genes (non-DEG). (B) Violin plots of the mean weighted methylation per gene across colonies per caste is plotted for either genes containing differentially expressed exons (DEE) or genes with non-differentially expressed exons (non-DEE). (C) Violin plots of the mean weighted methylation per exon across colonies per caste for DEE and non-DEE. The red dots represent the mean of each exon set along with error bars representing 95% confidence intervals of the mean. Each black dot is an individual exon. (D) Scatter plot of the difference in the mean weighted methylation level across colonies between castes plotted against the log₂ fold change in expression of differentially expressed genes between castes. Each dot represents a gene; only genes which have a methylation difference >0 are shown. The red dots indicate that the gene is also differentially methylated.

There was a significant overlap of genes found to be differentially expressed with those containing differentially expressed exons, 14 total (hypergeometric test; $P = 1.44 \times 10^{-10}$; Fig. 7A). All lists of overlapping genes can be found in Supporting Information 1.1.3.

HONEYBEE ORTHOLOGOUS DIFFERENTIALLY METHYLATED GENES

Custom honeybee and bumblebee putative ortholog databases were created from 15,314 and 10,339 annotated genes, respectively (Amel_4.5 GCA_000002195.1, Bter_1.0

Table 1. Summary statistics of the linear models used to check for differences in weighted methylation level between gene sets by taking into account reproductive status.

	Res.	Df	RSS	Df	Sum of square	F	P
Differentially expressed genes							
Interaction vs. main effects model	16487	—	833.1	—1	-2.98×10^{-4}	5.9×10^{-3}	0.93

*A significant P-value <0.05 . DEG, differentially expressed genes; DEE, differentially expressed exons. The interaction versus main effects models were tested using the *anova* function in R to assess the interaction effect between gene set and reproductive status.

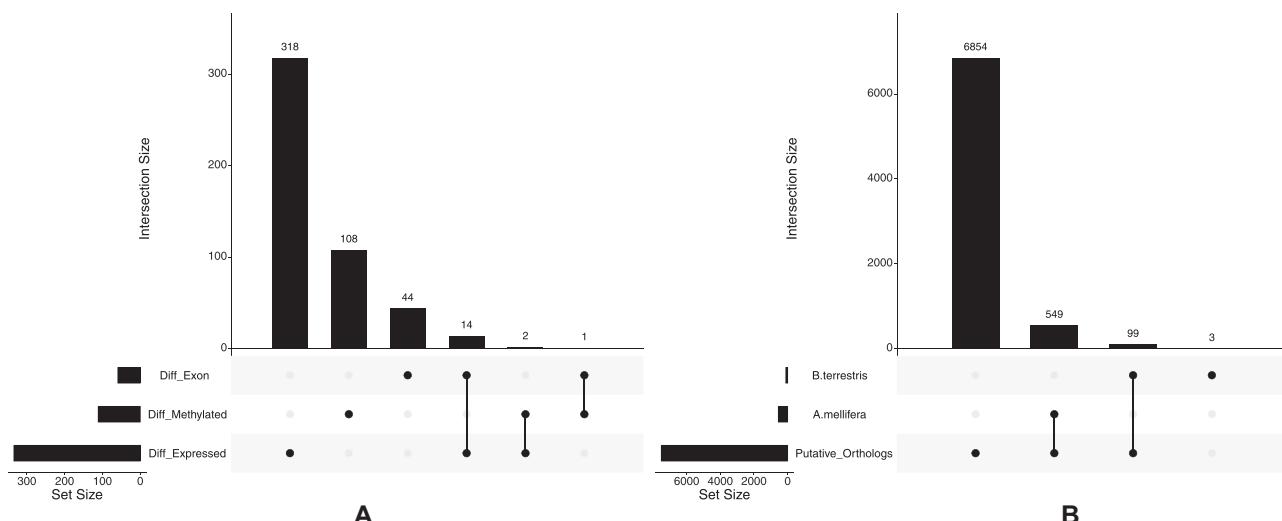

Figure 7. (A) UpSet plot showing the number of common genes between analyses. The set size indicates the number of genes in each category; differentially expressed, differentially methylated or genes containing a differentially expressed exon. The intersection size indicates the number of genes either unique to each set or the number common between sets. A single dot in the lower panel indicates the number of genes unique to the corresponding set and joining dots indicate the number of genes in common between the corresponding sets. (B) UpSet plot showing the number of putative orthologs between *A. mellifera* and *B. terrestris* along with the number of differentially methylated genes identified in Lyko et al. (2010) and in this study which are present in the putative ortholog database.

GCA_000214255.1). Note that 9,244 honeybee genes matched at least one bumblebee gene and 7,985 bumblebee genes matched at least one honeybee gene with an *e*-value of $<1 \times 10^{-3}$. A total of 7,345 genes made the same match in both blast searches. Of these genes, 392 matched more than one gene in one or both blasts and were therefore removed. This left a final putative ortholog list of 6,953 genes. A total of 99 of the 111 differentially methylated genes identified here were present in the final putative ortholog list, however none of them matched the 549 genes identified as

differentially methylated between honeybee reproductive castes by Lyko et al. (2010) (Fig. 7B).

Discussion

We have used whole genome bisulfite sequencing and gene expression libraries from the same individual *B. terrestris* workers to investigate the role of methylation in caste determination. We found both reproductive and sterile workers show similar

methylation patterns to other holometabolous insects. Methylation also has a similar relationship with gene expression compared to most other holometabolous insects currently studied, with more highly methylated genes showing higher levels of expression and lower levels of methylation being associated with differentially expressed genes. We found no methylation differences on a genomic scale between castes, however 111 genes were differentially methylated. These were involved in a variety of functions including reproductive related processes. We found no relationship between genes that are differentially expressed, or contain differential exon usage between castes with those that show differential methylation between castes. Finally, we also found no common putative orthologous genes differentially methylated between *B. terrestris* and *A. mellifera* reproductive castes.

This is the first data set to accurately quantify methylation at base-pair resolution for *B. terrestris* castes. It confirms low methylation levels throughout the genome as predicted by Sadd et al. (2015). These low levels along with enrichment for CpG methylation in coding regions are also seen in many social insect species, including *A. mellifera* (Lyko et al. 2010) and multiple ant species (Bonasio et al. 2012; Libbrecht et al. 2016). These trends are also seen more generally in holometabolous insects (Provataris et al. 2018). However, they are not completely conserved among all holometabolous insects, for example the primitively social wasp species *Polistes dominula* shows 6% CpG methylation (Weiner et al. 2013), and the highly social termite, *Zootermopsis nevadensis*, has exceptionally high methylation levels compared to the majority of insects (Bewick et al. 2017), with 12% CpG methylation, and methylation being just as common in introns as exons (Glastad et al. 2016).

Higher levels of CpG methylation are associated with higher levels of gene expression in both *B. terrestris* reproductive castes. This is also the case in some other social insects, with Figure 5A and 5D showing almost identical trends to those found in Bonasio et al. (2012), Patalano et al. (2015), and Libbrecht et al. (2016). Additionally, other social insect species show higher methylation in nondifferentially expressed genes as we found here, for example *Dinoponera quadriceps* (Patalano et al. 2015), *Polistes canadensis* (Patalano et al. 2015), *Zootermopsis nevadensis* (Glastad et al. 2016), and *Cerapachys biroi* (Libbrecht et al. 2016). Higher levels of methylation in more highly expressed genes and in nondifferentially expressed genes is thought to indicate a role for methylation in housekeeping genes in some holometabolous insects (Foret et al. 2009; Lyko et al. 2010; Bonasio et al. 2012; Wang et al. 2013; Provataris et al. 2018). High levels of gene body methylation is also found in highly expressed genes in plants; while currently the function is unknown, Zilberman (2017) hypothesizes that it functions to stabilize expression by reducing histone variants and Bewick and Schmitz (2017) hypothesize that it is a by-product of transposable element silencing.

We predicted that if methylation plays a role in reproductive caste determination, we would find differentially methylated genes between castes with reproductive related functions. We found 111 differentially methylated genes that include enriched GO terms for various reproductive-related processes; this suggests methylation has some association with the switch between sterility and reproduction in *B. terrestris*. This supports previous work that exposed *B. terrestris* to a chemical that decreases general methylation levels and found workers were more likely to become reproductive (Amarasinghe et al. 2014), however we did not find a difference in the genome-wide methylation levels of sterile and reproductive workers. It is also worth noting a worker classed as reproductive appeared to show a sterile transcriptional profile and this was included in the pool for the reproductive sample for colony J8. This will have “diluted” the strength of the methylation profile for this particular sample. It is therefore likely our data contain false negatives, meaning there may be differentially methylated genes between reproductive castes that do not appear in our data set.

Although we found differentially methylated genes between castes, we found no evidence for a relationship between methylation and gene expression in relation to reproductive and sterile workers. Only a small nonsignificant number of genes are both differentially methylated and differentially expressed between castes and there is no relationship between the degree of differential methylation and differential expression on a gene level. Previous research using the milkweed bug (*Oncopeltus fasciatus*) found knocking down *Dnmt1*, the gene responsible for DNA methylation maintenance, in ovary tissue with RNAi had no effect on gene expression, however these individuals could no longer reproduce (Bewick et al. 2019). This suggests methylation may play an alternative role, rather than direct regulation of gene expression, in reproduction of some insects. Bewick et al. (2019) suggest this role may be the regulation of genome stability and/or the regulation of vital cellular processes. The variety of GO terms involved in biological processes we obtained for the differentially methylated genes between castes supports this idea.

Additionally, we observed high intercolony variation in methylation, however we did not have sufficient replicates to test for exact differences between colonies. High intercolony variation could suggest that methylation may also play a role in the adaptive abilities of *B. terrestris*. Stable environmentally induced “epialleles” have been proposed to act as an additional layer of information for which selection can act upon (Flores et al. 2013). However, we currently do not know if *B. terrestris* methylation shows transgenerational inheritance or whether a large proportion is wiped during development, as in mammals (Messerschmidt et al. 2014).

It has also been suggested methylation may regulate alternative splicing, rather than expression in some insects (Glastad et al.

2011). We found no evidence here for the role of exon methylation in exonic expression differences between castes. Previous research using honeybees however did find an association between methylation and caste specific alternative splicing. Methylation differences between queens and workers in *A. mellifera* have been associated with caste-specific splicing events (Lyko et al. 2010). Additionally, a knock-down of *Dnmt3* by RNA interference was found to affect alternative splicing patterns in *A. mellifera*, with decreased methylation levels being directly related to exon skipping and intron retention (Li-Byarlay et al. 2013). However, another social insect species, the primitively social wasp, *Polistes dominula*, has also shown no direct association between methylation and alternative splicing (Standage et al. 2016), however this species shows extremely low genome methylation and appears to lack the *Dnmt3* gene responsible for de novo methylation, suggesting that the link between methylation and alternative splicing in insects is variable.

Exon methylation has been shown to play a role in histone modifications and nucleosome stability in mammals (Jones 2012; Singer et al. 2015). These modifications have the ability to affect alternative splicing patterns through RNA polymerase accessibility, meaning while changes in DNA methylation may not be observed as directly related to alternative splicing, it is possible these changes have a downstream effect leading to transcriptional changes (Hunt et al. 2013). The analysis of the relationship between methylation and alternative splicing done here could be elaborated on further to include noncaste specific splicing sites and to also potentially identify the role of exon methylation in other epigenetic processes, which may themselves lead to alternative splicing.

It is also worth noting other epigenetic mechanisms may play a role in caste determination, for example microRNAs have been associated with caste switching in *A. mellifera* (Ashby et al. 2016). Additionally, Simola et al. (2016) found histone acetylation differences between worker castes of *Camponotus floridanus*. They inhibited histone acetylation and found this caused the major worker caste to behave more like a minor worker. This same species has also been shown to have caste specific methylation profiles (Bonasio et al. 2012). These examples indicate that it is likely an interplay between multiple mechanisms that ultimately cause social insect caste differentiation, again supported by the fact we find no association between methylation and caste-specific alternative splicing.

Our final prediction was that differentially methylated genes between worker *B. terrestris* castes would be similar to those found to be differentially methylated between *A. mellifera* reproductive castes if methylation was involved in caste determination in Hymenoptera; we did not find any putative orthologous in common. This supports the idea in Bewick et al. (2019) that methylation may not directly influence caste determination. However, the

differentially methylated gene list obtained for *A. mellifera* used queen samples to represent the reproductive caste (Lyko et al. 2010), whereas here reproductive worker samples were used; this could also explain the lack of agreement.

Considerably more experimental research is needed to better define the relationship between epigenetic processes and caste determination in social insects. Future work should focus on the consequences of experimental methylation removal or addition (Pegoraro et al. 2017), as well as exploring additional epigenetic mechanisms to attempt to identify a full pathway leading to reproductive caste differences. For example, CRISPR has recently been used to knockout two sex-determining genes in *A. mellifera* causing individuals to change gender (McAfee et al. 2019). This technology has also been adapted to be able to change the methylation state of a given loci (Vojta et al. 2016), allowing the possibility of exploring the function of methylation in specific genes.

Overall, we have found that the *B. terrestris* methylome appears similar to some other holometabolous insects in terms of overall levels and the relationship with gene expression. We found no genome-wide methylation differences between reproductive castes, however we did find differentially methylated genes between reproductive castes, with GO terms enriched in many biological processes including reproduction. These results combined with previous research (Amarasinghe et al. 2014) indicate an association between methylation and reproductive caste differences in *B. terrestris*. However, it is clear, owing to the lack of consistency between differentially methylated genes and differentially expressed genes, methylation is not directly responsible for the associated changes in gene expression leading to the different reproductive phenotypes in *B. terrestris*. Additionally, the lack of similarity between differentially methylated genes between castes in *B. terrestris* and between castes in *A. mellifera* suggests that methylation may not directly contribute to caste determination in some Hymenoptera. Future work should focus on the experimental manipulation of epigenetic processes, such as methylation, in social insects to clarify functional roles within and across species.

AUTHOR CONTRIBUTIONS

EBM conceived the study. HM and ZNL conducted the experiment. HM analyzed the data and wrote the initial manuscript. All authors contributed to and reviewed the final manuscript.

ACKNOWLEDGMENTS

Thank you to Dr. Ben Hunt and Boris Berkhout for important advice and discussion regarding data analysis. Thank you to Dr. Ezio Rosato for providing valuable discussion. Thank you to the reviewers for helpful comments and suggestions. This research used the ALICE2 High Performance Computing Facility at the University of Leicester. HM was supported by a NERC CENTA DTP studentship. ZNL was supported by a BBSRC MIBTP DTP studentship. EBM was funded by NERC grant NE/N010019/1. The authors declare no conflict of interests.

DATA ARCHIVING

Data have been deposited in GenBank under NCBI BioProject: PRJNA533306. All code will also be made available at: <https://doi.org/10.5281/zenodo.2394171>.

Appendix: Chapter 4

B.1 Additional figures

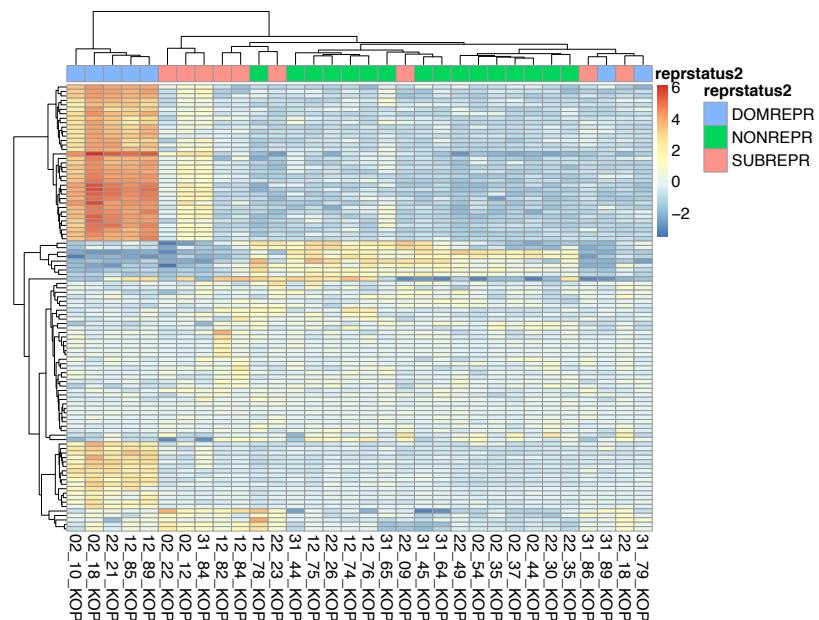

Figure B.1: Heatmaps showing the 100 most differentially expressed genes between dominant reproductive workers and sterile workers, with subordinate reproductive workers also shown. Sample names along the bottom refer to the colony of origin, the individual and the tissue type and KOP = head. Red indicates up-regulation and blue indicates down-regulation.

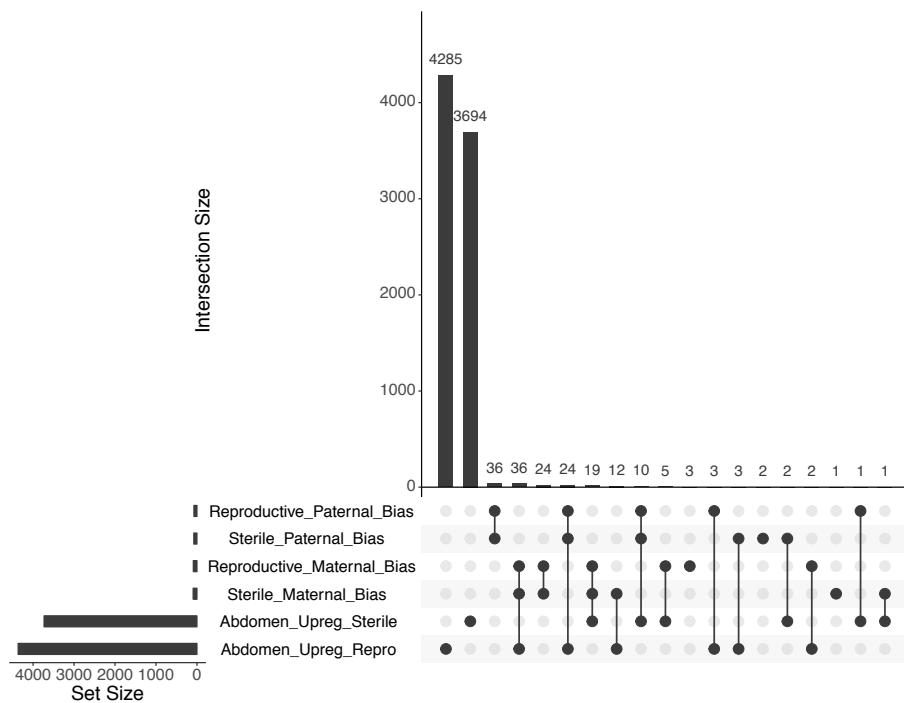

Figure B.2: Overlapping genes showing parent-of-origin expression in reproductive (queen-right) and sterile (queen-less) workers with genes showing differential expression in abdomen tissue. The set size indicates the number of genes in each list. The intersection size shows how many genes the corresponding lists have in common. A single dot refers to the number of genes unique to each list.

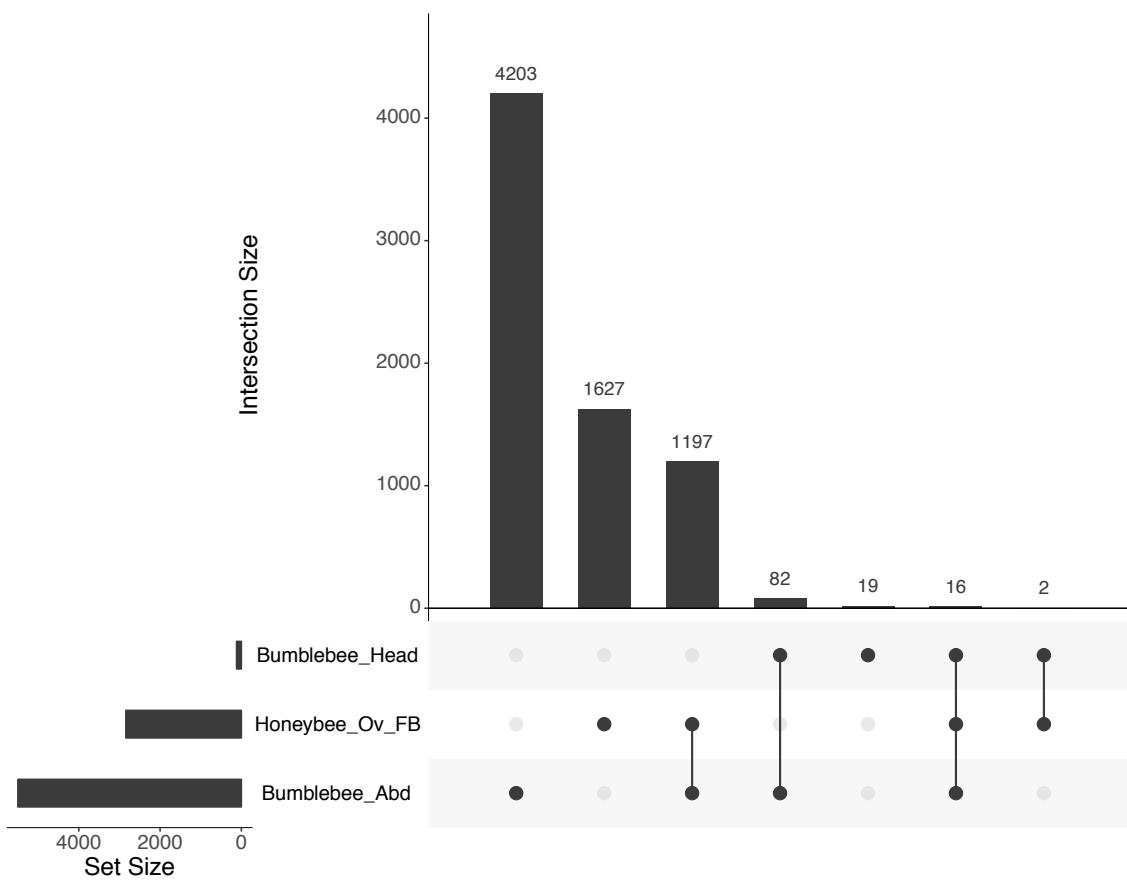

Figure B.3: Overlapping genes showing differential expression between reproductive (queen-right) and sterile (queen-less) workers of *B. terrestris* head and abdomen tissue and *A. mellifera* ovary/fatbody tissue (genes identified in Galbraith *et al.* (2016a)). The set size indicates the number of genes in each list. The intersection size shows how many genes the corresponding lists have in common. A single dot refers to the number of genes unique to each list.

Appendix C

Appendix: Chapter 5

C.1 Poor quality sequencing comparison

All samples were originally sequenced by Liverpool Genomics. The data received were of too poor quality to obtain any reliable results. The first attempt at sequencing produced considerable methylation-bias within the reads (Fig. C.1). This is where a cytosine is more likely to be called as ‘methylated’ if it occurs in a certain position within a given read. This bias decreased upon the second attempt at sequencing by Liverpool Genomics. However, the reads still contained considerable bias. The final data set used, generated from BGI, had very little bias (Fig. C.1). As well as the removal of an unacceptable level of false positives within the data, BGI also provided slightly more data with greater mapping and less duplication, Table C.1.

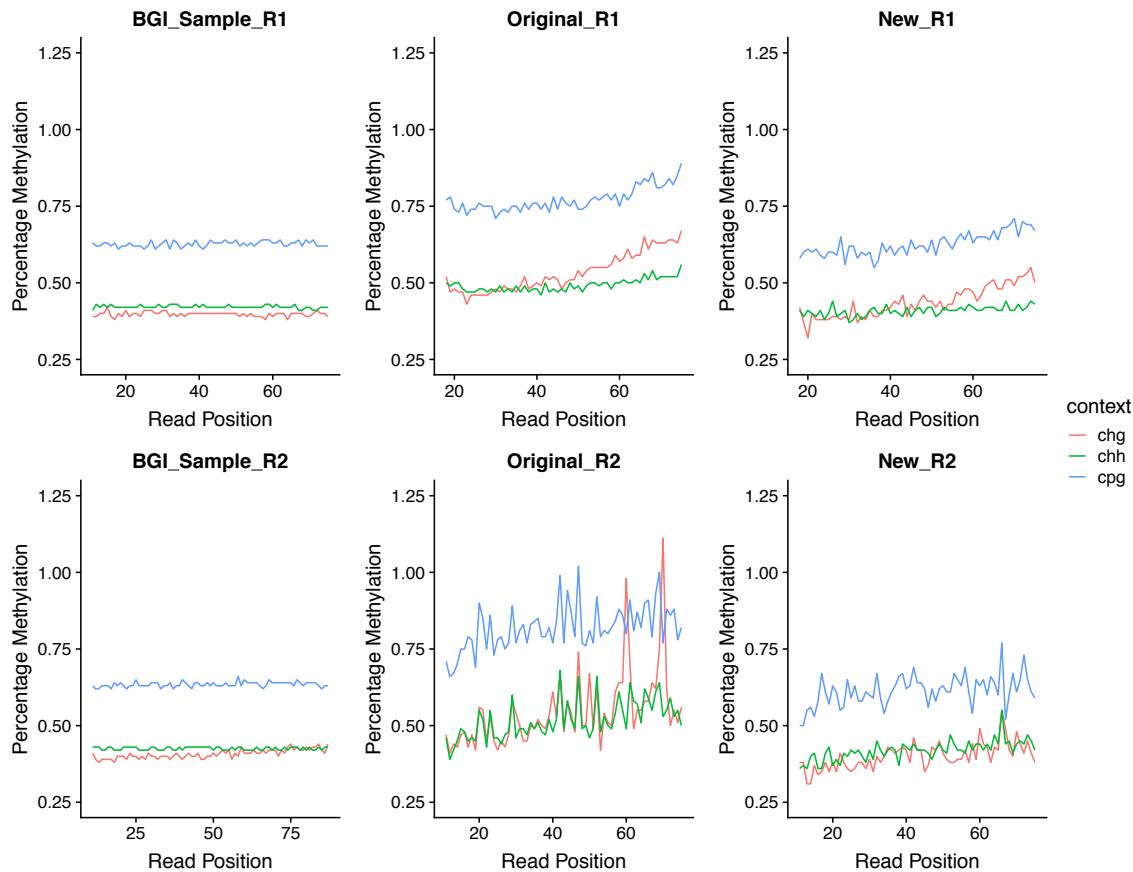

Figure C.1: M-bias plots for sample W08 (pooled worker sample from colony 08). M-bias plots show the average percentage of methylated bases per read position. Read 1 and read 2 are shown separately. All reads have been pre-trimmed to remove 3' base bias. ‘Original’ refers to the first round of sequencing generated by Liverpool Genomics. ‘New’ refers to the second round of sequencing carried out by Liverpool Genomics. ‘BGI’ refers to the sequencing carried out by BGI.

Table C.1: Summary statistics of the data generated by Liverpool Genomics and BGI. All statistics are a mean across all samples.

	Liverpool	BGI
Total Reads	30166644	30391345
Unique Mapping (%)	56	60
Total Mapped Reads	16810138	18194268
Duplicated Reads (%)	45	34
Final Reads	9278762	11897611
Original Data Remaining (%)	30	40
Genome Coverage	9.7	12.44

Appendix D

Appendix: Chapter 6

D.1 High-hardness COMBO

Protocol for creating the high-hardness culturing medium, modified from the University of Birmingham, School of Biosciences, Daphnia Facility, Standard Operating Procedure version 1.

Table D.1: Main stock solutions needed to create high-hardness COMBO media for culturing *Daphnia magna*.

Component Number	Compound	Chemical Formula	Concentration (g/L)
1	Calcium chloride dihydrate	CaCl ₂ .2H ₂ O	110.28
2	Magnesium sulphate heptahydrate	MgSO ₄ .7H ₂ O	113.5
3	Potassium phosphate dibasic	K ₂ HPO ₄	1.742
4	Sodium nitrate	NaNO ₃	17.0
5	Sodium metasilicate nonahydrate	Na ₂ SiO ₃ .9H ₂ O	13.267
6	Boric acid	H ₃ BO ₃	24.0
7	Potassium chloride	KCl	5.96
8	Sodium bicarbonate	NaHCO ₃	63.0
9	Sodium selenite	NaSeO ₃	40μg/L

Table D.2: Stock solutions required for Animate. All stock solutions are to be dispensed into 1.5ml aliquots in Eppendorf tubes and stored at -20°C.

Component Number	Compound	Chemical Formula	Concentration (g/L)
10	Lithium chloride	LiCl	31
11	Rubidium chloride	RbCl	7.0
12	Strontium chloride hexahydrate	SrCl ₂ .6H ₂ O	15
13	Sodium bromide	NaBr	1.6
14	Potassium iodide	KI	0.33

To prepare the Animate stock solution add 1ml of each of stock solutions **10** to **14** to approximately 500ml of dH₂O and adjust the volume to 1 litre. The Animate stock solution should be stored at approximately 5°C prior to use.

Table D.3: Stock solutions required for the VIM. All stock solutions are to be dispensed into 1.5ml aliquots in Eppendorf tubes and stored at -20°C. Additionally, the B12 should be covered with foil to avoid light exposure.

Component Number	Compound	Preparation
15	Biotin (d-biotin)	10mg into 96ml of dH ₂ O
16	B12 (cyanocobalamin)	10mg into 89ml of dH ₂ O

To prepare the vitamin solution, remove one aliquot of Biotin and B12 from the freezer and allow to defrost. To a 50ml volumetric flask, add 30ml of dH₂O, 0.5ml biotin, 0.5ml B12 and 10mg of Thiamine HCl. Adjust the volume to 50ml with dH₂O then transfer the whole volume to a Duran bottle covered with foil to shield from light and store at approximately 5°C for up to a maximum of 1 week.

To prepare 4L of high-hardness COMBO, add 4ml of stock solutions **1** to **7**, 8ml of stock solution **8** and 200 μ l of stock solution **9** to 3.5L of dH₂O then adjust the volume to 4 litres. Aerate the medium for approximately 24 hours then adjust the pH to 7.6 – 7.8 prior to the addition of 4ml of Animate and 2ml of VIM stock solutions.

D.2 DNA extraction: optimised protocol

Protocol optimised using the Epicenter MasterPure™ Complete DNA and RNA Purification Kit by Dr. Leda Mirbahai.

Reagents:

- 70% Ethanol (On ice)
- Isopropanol (On ice)
- RNase A (1mg/ml)

- Proteinase K ($50\mu\text{g}/\mu\text{l}$)
- MPC Protein precipitation buffer (from kit)
- 1x Lysis buffer (from kit)
- Liquid nitrogen

Additional equipment:

- Heating block at 37°C
- Heating block at 65°C
- Centrifuge at 4°C

Protocol:

1. Add $300\mu\text{l}$ of the lysis buffer and $1\mu\text{l}$ of proteinase K to a tube of around 20 4-day old *Daphnia*.
2. Carry out tissue lysis using a Geno/Grinder[®]: 30seconds at 1750rpm.
3. Transfer the tube to a heating block set at 65°C , and incubate for 15 minutes.
Invert the tube three times during this time.
4. Cool the samples to 37°C .
5. Add $4\mu\text{l}$ of 1mg/ml RNase A.
6. Place the tube on heating block at 37°C for 30 minutes.
7. Place on ice for five minutes.
8. Add $175\mu\text{l}$ of MPC protein reagent and mix well by pipetting it up and down several times.
9. Centrifuge at 4°C for 10 minutes at 10,000g.
10. Transfer the supernatant to a clean tube.
11. Add $500\mu\text{l}$ of ice cold isopropanol and mix well by pipetting.
12. Centrifuge at 4°C for 10 minutes at 10,000g.

13. Remove and discard the supernatant, the DNA should now be a visible pellet.
14. Add 500 μ l of ice cold 70% ethanol.
15. Invert the tube once without disturbing the pellet.
16. Centrifuge at 4°C for 10 minutes at 10,000g.
17. Discard the liquid.
18. Add 500 μ l of ice cold 70% ethanol.
19. Invert the tube once without disturbing the pellet.
20. Centrifuge at 4°C for 10 minutes at 10,000g.
21. Remove all liquid (use a 10 μ l pipette to remove as much as possible).
22. Leave the tubes on a bench with the lids open to dry for 30 minutes.
23. Add 30 μ l of RNase/DNase free water, dissolve and quantify.

Supplementary 1.0.1: Quantity and quality values for all extracted samples. 260/280 and 260/230 values were determined using a Nanodrop 2000. Final volume was estimated, taking into account the maximum volume loss during the elution step of the DNA extraction procedure and QUBIT concentration levels. Sample names refer to unique colony and reproductive status (R= reproductive, NR= non-reproductive).

	Nanodrop	QUBIT				
Sample	Concentration (ng/ μ l)	Concentration (ng/ μ l)	Final Volume (μ l)	Total DNA (μ g)	260/280	260/230
J1_R	143.9	13.8	100	1.38	2.1	1.8
J1_NR	136.4	13.5	92.5	1.25	2.11	1.91
J5_R	146	17.3	83.5	1.44	2.05	1.76
J5_NR	139.2	15.1	100	1.51	2.09	1.95
J8_R	141.2	12.8	100	1.28	2.08	1.73
J8_NR	145.6	19	100	1.9	2.08	1.86

Supplementary 1.0.2: Quantity and quality values for all extracted RNA samples, generated using an Agilent 2100. RIN (RNA integrity score) indicates the level of degradation of the sample, 0 being full degraded and 10 being fully intact. Sample names refer to unique colony and reproductive status (R= reproductive, NR= non-reproductive).

Sample	Concentration (ng/ μ l)	Final Volume (μ l)	Total RNA (μ g)	RIN
J1_3	128	30	3.84	6.9
J1_5	151	34	5.13	8.4
J1_6	156	33	5.15	8.2

GO:1903421	regulation of synaptic vesicle recycling	0.00%	-2.3748
GO:0031442	positive regulation of mRNA 3'-end processing	0.00%	-2.3748

Supplementary information 1.0.4: list of differentially methylated CpGs between reproductive and sterile workers, a positive methylation difference indicates hypermethylation in sterile workers.

gene_id	chromosome	CpG_position	p-value	q-value	methylation_difference

Supplementary 10.6: Results of the post-hoc Dunn's test; p-values have been corrected for multiple testing using the Benjamini-Hochberg method. * indicates a significant difference ($p < 0.05$) in the weighted methylation of the features compared, using weighted methylation calculated from all samples.

Supplementary 10.8: List of the GO terms associated with differentially methylated genes between castes.

term_ID	description	frequency	log10 p-value
GO:0016043	cellular component organization	7.24%	-1.69
GO:0009605	response to external stimulus	1.37%	-1.4644
GO:0035335	peptidyl-tyrosine dephosphorylation	0.26%	-2.2548
GO:0051321	meiotic cell cycle	0.18%	-1.595
GO:0045936	negative regulation of phosphate metabolic process	0.18%	-1.3538
GO:0050776	regulation of immune response	0.15%	-1.6772
GO:0031400	negative regulation of protein modification process	0.15%	-1.3984
GO:0016050	vesicle organization	0.13%	-1.5177
GO:0006661	phosphatidylinositol biosynthetic process	0.12%	-1.8891
GO:0007062	sister chromatid cohesion	0.10%	-1.4104
GO:0000027	ribosomal large subunit assembly	0.08%	-1.3404
GO:0002757	immune response-activating signal transduction	0.07%	-2.077
GO:0001731	formation of translation preinitiation complex	0.07%	-1.4186
GO:0010631	epithelial cell migration	0.06%	-1.9574
GO:0007229	integrin-mediated signalling pathway	0.06%	-2.1509
GO:0090130	tissue migration	0.06%	-1.8903
GO:0007020	microtubule nucleation	0.04%	-1.6068
GO:0002218	activation of innate immune response	0.04%	-1.7455
GO:0045995	regulation of embryonic development	0.04%	-1.3213
GO:0001649	osteoblast differentiation	0.04%	-1.6201
GO:0043409	negative regulation of MAPK cascade	0.04%	-1.3647
GO:1903725	regulation of phospholipid metabolic process	0.03%	-2.0269
GO:0002221	pattern recognition receptor signaling pathway	0.03%	-2.2548
GO:0043550	regulation of lipid kinase activity	0.02%	-1.8598
GO:0010594	regulation of endothelial cell migration	0.02%	-1.6068
GO:0042149	cellular response to glucose starvation	0.02%	-1.8598
GO:0034446	substrate adhesion-dependent cell spreading	0.02%	-2.1509

GO:0001570	vasculogenesis	0.02%	-1.6068
GO:0000076	DNA replication checkpoint	0.02%	-1.5066
GO:0051897	positive regulation of protein kinase B signaling	0.02%	-1.6068
GO:0043279	response to alkaloid	0.02%	-1.3404
GO:0043552	positive regulation of phosphatidylinositol 3-kinase activity	0.01%	-2.9996
GO:0050435	beta-amyloid metabolic process	0.01%	-1.4975
GO:0006509	membrane protein ectodomain proteolysis	0.01%	-1.7227
GO:0045022	early endosome to late endosome transport	0.01%	-1.7227
GO:0031638	zymogen activation	0.01%	-1.4186
GO:0042572	retinol metabolic process	0.01%	-1.4975
GO:0031938	regulation of chromatin silencing at telomere	0.01%	-1.4975
GO:1900087	positive regulation of G1/S transition of mitotic cell cycle	0.01%	-1.5066
GO:0048208	COPII vesicle coating	0.01%	-1.7227
GO:0048199	vesicle targeting, to, from or within Golgi	0.01%	-1.6068
GO:0006267	pre-replicative complex assembly involved in nuclear cell cycle DNA replication	0.01%	-1.4975
GO:0033627	cell adhesion mediated by integrin	0.01%	-1.6068
GO:0002504	antigen processing and presentation of peptide or polysaccharide antigen via MHC class II	0.01%	-1.4186
GO:0002474	antigen processing and presentation of peptide antigen via MHC class I	0.01%	-1.5066
GO:0036388	pre-replicative complex assembly	0.01%	-1.4975
GO:0051647	nucleus localization	0.01%	-1.3404
GO:0051415	interphase microtubule nucleation by interphase microtubule organizing center	0.00%	-2.9996
GO:0003365	establishment of cell polarity involved in amoeboidal cell migration	0.00%	-1.4975
GO:0038128	ERBB2 signaling pathway	0.00%	-2.9996
GO:2000209	regulation of anoikis	0.00%	-2.5316
GO:1902954	regulation of early endosome to recycling endosome transport	0.00%	-1.4975
GO:0032495	response to muramyl dipeptide	0.00%	-1.4975
GO:0032487	regulation of Rap protein signal transduction	0.00%	-1.4975
GO:0044026	DNA hypermethylation	0.00%	-1.4975
GO:0018406	protein C-linked glycosylation via 2'-alpha-mannosyl-L-tryptophan	0.00%	-1.4975
GO:0044313	protein K6-linked deubiquitination	0.00%	-1.4975

GO:0034421	post-translational protein acetylation	0.00%	-1.4975

Supplementary 1.1.2: List of enriched GO terms associated with genes containing differentially used exons between castes.

term_ID	description	frequency	log10 p-value
GO:0044406	adhesion of symbiont to host	0.01%	-1.7326
GO:0048678	response to axon injury	0.01%	-2.3701
GO:1903034	regulation of response to wounding	0.03%	-2.149
GO:1903725	regulation of phospholipid metabolic process	0.03%	-2.7004
GO:0045834	positive regulation of lipid metabolic process	0.03%	-1.707
GO:0043552	positive regulation of phosphatidylinositol 3-kinase activity	0.01%	-1.7326
GO:0030242	pexophagy	0.01%	-1.609
GO:0035609	C-terminal protein deglutamylatation	0.00%	-2.2071
GO:0035610	protein side chain deglutamylation	0.00%	-2.2071
GO:0042160	lipoprotein modification	0.00%	-1.7326
GO:0008283	cell proliferation	0.39%	-1.3046
GO:1903475	mitotic actomyosin contractile ring assembly	0.01%	-2.2071
GO:1902410	mitotic cytokinetic process	0.05%	-1.609
GO:0006545	glycine biosynthetic process	0.08%	-1.609
GO:1904059	regulation of locomotor rhythm	0.00%	-1.7326
GO:0042632	cholesterol homeostasis	0.02%	-2.3174
GO:1904589	regulation of protein import	0.04%	-2.3701
GO:1900180	regulation of protein localization to nucleus	0.05%	-1.8921
GO:0042308	negative regulation of protein import into nucleus	0.01%	-1.4355
GO:0046822	regulation of nucleocytoplasmic transport	0.05%	-1.707
GO:0006828	manganese ion transport	0.02%	-1.4355
GO:0045324	late endosome to vacuole transport	0.03%	-1.3132
GO:0098581	detection of external biotic stimulus	0.00%	-2.2071
GO:0032497	detection of lipopolysaccharide	0.00%	-2.2071
GO:0034334	adherens junction maintenance	0.00%	-1.5134
GO:0006006	glucose metabolic process	0.43%	-1.5504

GO:0034368	protein-lipid complex remodeling	0.01%	-1.609
GO:0034375	high-density lipoprotein particle remodeling	0.00%	-1.609
GO:0071827	plasma lipoprotein particle organization	0.01%	-1.4355
GO:0031104	dendrite regeneration	0.00%	-2.2071
GO:0048680	positive regulation of axon regeneration	0.00%	-1.9074
GO:0070570	regulation of neuron projection regeneration	0.01%	-1.4355
GO:0031102	neuron projection regeneration	0.01%	-1.4462
GO:0014012	peripheral nervous system axon regeneration	0.00%	-1.609
GO:0009605	response to external stimulus	1.37%	-1.3465
GO:0043654	recognition of apoptotic cell	0.00%	-2.2071
GO:0034162	toll-like receptor 9 signaling pathway	0.00%	-1.9074
GO:0006702	androgen biosynthetic process	0.00%	-1.7326
GO:0019102	male somatic sex determination	0.00%	-1.9074
GO:0034384	high-density lipoprotein particle clearance	0.00%	-2.2071
GO:0034383	low-density lipoprotein particle clearance	0.00%	-1.4355
GO:0006796	phosphate-containing compound metabolic process	13.11%	-1.4436
GO:0035298	regulation of Malpighian tubule size	0.00%	-2.2071
GO:0006707	cholesterol catabolic process	0.00%	-2.2071
GO:1902775	mitochondrial large ribosomal subunit assembly	0.00%	-1.9074
GO:0060292	long term synaptic depression	0.00%	-1.9074
GO:0008362	chitin-based embryonic cuticle biosynthetic process	0.00%	-1.4355
GO:0035461	vitamin transmembrane transport	0.00%	-2.2071
GO:0071896	protein localization to adherens junction	0.00%	-1.609
GO:0051000	positive regulation of nitric-oxide synthase activity	0.00%	-1.7326
GO:0032768	regulation of monooxygenase activity	0.01%	-1.3699
GO:0051353	positive regulation of oxidoreductase activity	0.01%	-1.3699
GO:0000768	syncytium formation by plasma membrane fusion	0.01%	-1.8345
GO:1901739	regulation of myoblast fusion	0.00%	-1.3699
GO:0007601	visual perception	0.05%	-1.9756
GO:0050906	detection of stimulus involved in sensory perception	0.29%	-1.5207

GO:0007600	sensory perception	0.43%	-1.4383
GO:0046460	neutral lipid biosynthetic process	0.02%	-2.5521
GO:0006639	acylglycerol metabolic process	0.04%	-1.6838
GO:0006651	diacylglycerol biosynthetic process	0.00%	-1.609
GO:0010867	positive regulation of triglyceride biosynthetic process	0.00%	-1.4355
GO:0019432	triglyceride biosynthetic process	0.02%	-1.5241
GO:2000035	regulation of stem cell division	0.00%	-1.7326
GO:0031848	protection from non-homologous end joining at telomere	0.00%	-1.609
GO:0015920	lipopolysaccharide transport	0.03%	-2.2071
GO:0070508	cholesterol import	0.00%	-1.9074
GO:0043691	reverse cholesterol transport	0.00%	-1.609
GO:0019915	sterol storage	0.03%	-1.8073
GO:0035382	sterol transmembrane transport	0.16%	-2.2071
GO:0014902	myotube differentiation	0.03%	-1.707

GO:1902221	erythrose 4-phosphate/phosphoenolpyruvate family amino acid metabolic process	0.08%	-1.4355
GO:0007164	establishment of tissue polarity	0.02%	-1.3725
GO:0016476	regulation of embryonic cell shape	0.00%	-1.4355
GO:0046663	dorsal closure, leading edge cell differentiation	0.00%	-1.7326
GO:0007395	dorsal closure, spreading of leading edge cells	0.00%	-1.609
GO:0030589	pseudocleavage involved in syncytial blastoderm formation	0.00%	-1.5134
GO:0033540	fatty acid beta-oxidation using acyl-CoA oxidase	0.00%	-1.3699
GO:0007374	posterior midgut invagination	0.00%	-2.2071
GO:0007370	ventral furrow formation	0.00%	-1.609
GO:0007377	germ-band extension	0.00%	-1.5134
GO:2000405	negative regulation of T cell migration	0.00%	-1.7326
GO:0002686	negative regulation of leukocyte migration	0.01%	-1.3699
GO:2000401	regulation of lymphocyte migration	0.01%	-1.4355
GO:0090251	protein localization involved in establishment of planar polarity	0.00%	-2.2071
GO:0042249	establishment of planar polarity of embryonic epithelium	0.00%	-1.609

GO:0001737	establishment of imaginal disc-derived wing hair orientation	0.00%	-1.3132
GO:0034442	regulation of lipoprotein oxidation	0.00%	-1.7326
GO:0050748	negative regulation of lipoprotein metabolic process	0.00%	-1.7326
GO:0060588	negative regulation of lipoprotein lipid oxidation	0.00%	-1.7326
GO:0007089	traversing start control point of mitotic cell cycle	0.00%	-1.9074
GO:0090254	cell elongation involved in imaginal disc-derived wing morphogenesis	0.00%	-1.9074
GO:0044255	cellular lipid metabolic process	2.70%	-2.3169
GO:0035149	lumen formation, open tracheal system	0.00%	-1.609
GO:0010642	negative regulation of platelet-derived growth factor receptor signaling pathway	0.00%	-1.5134
GO:0016054	organic acid catabolic process	0.95%	-1.7469
GO:0009063	cellular amino acid catabolic process	0.65%	-1.3578
GO:0021702	cerebellar Purkinje cell differentiation	0.00%	-1.7326
GO:0021692	cerebellar Purkinje cell layer morphogenesis	0.00%	-1.4355
GO:0021697	cerebellar cortex formation	0.01%	-1.4355
GO:0046622	positive regulation of organ growth	0.01%	-1.4355
GO:0003008	system process	0.66%	-1.6751
GO:0010631	epithelial cell migration	0.06%	-1.5931
GO:0090130	tissue migration	0.06%	-1.5609
GO:0050884	neuromuscular process controlling posture	0.00%	-1.7326
GO:0010810	regulation of cell-substrate adhesion	0.04%	-1.5978
GO:2000098	negative regulation of smooth muscle cell-matrix adhesion	0.00%	-1.7326
GO:0051895	negative regulation of focal adhesion assembly	0.00%	-1.4355
GO:0006572	tyrosine catabolic process	0.01%	-1.5134
GO:0006559	L-phenylalanine catabolic process	0.03%	-1.4355
GO:0090596	sensory organ morphogenesis	0.08%	-1.6023
GO:0030950	establishment or maintenance of actin cytoskeleton polarity	0.01%	-1.7326
GO:0045199	maintenance of epithelial cell apical/basal polarity	0.00%	-1.5134
GO:0034440	lipid oxidation	0.09%	-1.6614
GO:0050910	detection of mechanical stimulus involved in sensory perception of sound	0.00%	-1.9074
GO:0050982	detection of mechanical stimulus	0.01%	-1.3699

GO:0010886	positive regulation of cholesterol storage	0.00%	-1.9074
GO:1900016	negative regulation of cytokine production involved in inflammatory response	0.00%	-1.609
GO:0071638	negative regulation of monocyte chemotactic protein-1 production	0.00%	-1.5134
GO:0006706	steroid catabolic process	0.00%	-1.7326
GO:0055088	lipid homeostasis	0.04%	-1.7308
GO:0070593	dendrite self-avoidance	0.00%	-1.609

GO:0045321	leukocyte activation	0.15%	-1.3041
GO:0033151	V(D)J recombination	0.00%	-1.4355
GO:0051480	regulation of cytosolic calcium ion concentration	0.06%	-1.5778
GO:0010899	regulation of phosphatidylcholine catabolic process	0.00%	-2.2071
GO:0046475	glycerophospholipid catabolic process	0.01%	-1.3699
GO:0045017	glycerolipid biosynthetic process	0.30%	-2.0416
GO:0006567	threonine catabolic process	0.04%	-1.609
GO:0048699	generation of neurons	0.37%	-1.5505
GO:0048666	neuron development	0.27%	-1.5976

Supplementary 1.1.3: Lists of overlapping genes from all analyses.

Genes both differentially methylated and differentially expressed between reproductive and sterile workers.

LOC100647553 SWI/SNF complex subunit SMARCC2

LOC100647451 retinoblastoma-binding protein 5 homolog

Genes both differentially methylated and containing a differentially expressed exon between reproductive and sterile workers.

LOC100649679 phosphoinositide 3-kinase regulatory subunit 4

Genes both differentially expressed and containing a differentially expressed exon between reproductive and sterile workers.

- LOC100644055 uncharacterized
- LOC100646942 venom acid phosphatase Acph-1
- LOC100648012 replication factor C subunit 1
- LOC100648602 uncharacterized
- LOC100648955 probable peroxisomal acyl-coenzyme A oxidase 1
- LOC100648980 insulin-like growth factor I, juvenile form
- LOC100649392 flavin-containing monooxygenase FMO GS-OX-like 2
- LOC100650035 protein artichoke
- LOC100650646 SPARC-related modular calcium-binding protein 2
- LOC100650865 allatotropin receptor
- LOC100651787 3-hydroxy-3-methylglutaryl-coenzyme A reductase
- LOC100652301 serine protease inhibitor 3/4
- LOC105666289 uncharacterized
- LOC110119151 probable low-specificity L-threonine aldolase 1

Chapter 3: supplementary

Supplementary 3.0.0: mapping statistics for all samples aligned to the Bter_1.0 reference genome using STAR.

Sample	Mapping Percentage	Unique Mapped Reads

Supplementary 3.0.2: Enriched GO terms for genes showing allele-specific expression in either both castes, just reproductive workers or just sterile workers.

Allelically expressed genes in both castes.

term_ID	description	frequency	log10 p-value
GO:0000469	cleavage involved in rRNA processing	0.05%	-2.3396
GO:0046960	sensitization	0.00%	-1.9186
GO:0072488	ammonium transmembrane transport	0.09%	-1.9186
GO:2000117	negative regulation of cysteine-type endopeptidase activity	0.02%	-2.3396
GO:0010466	negative regulation of peptidase activity	0.17%	-1.8288
GO:2001268	negative regulation of cysteine-type endopeptidase activity involved in apoptotic signaling pathway	0.00%	-2.2184
GO:1900117	regulation of execution phase of apoptosis	0.01%	-1.5245
GO:2001271	negative regulation of cysteine-type endopeptidase activity involved in execution phase of apoptosis	0.00%	-1.7438
GO:0043281	regulation of cysteine-type endopeptidase activity involved in apoptotic process	0.04%	-1.5236
GO:0006921	cellular component disassembly involved in execution phase of apoptosis	0.01%	-1.3242
GO:0044247	cellular polysaccharide catabolic process	0.10%	-1.381
GO:0009251	glucan catabolic process	0.10%	-1.381
GO:0061484	hematopoietic stem cell homeostasis	0.00%	-1.7438
GO:0044205	'de novo' UMP biosynthetic process	0.22%	-1.7438
GO:0046049	UMP metabolic process	0.27%	-1.5245
GO:0009174	pyrimidine ribonucleoside monophosphate biosynthetic process	0.28%	-1.4466
GO:0006207	'de novo' pyrimidine nucleobase biosynthetic process	0.19%	-1.4466
GO:0090263	positive regulation of canonical Wnt signaling pathway	0.02%	-2.2435
GO:0030111	regulation of Wnt signaling pathway	0.07%	-1.9596
GO:0198738	cell-cell signaling by wnt	0.14%	-1.4615
GO:0010378	temperature compensation of the circadian clock	0.00%	-1.7438

Supplementary 3.0.6: Enriched GO terms for genes showing allele-specific methylation in either both castes, just reproductive workers or just sterile workers.

term_ID	description	Allelically methylated genes in both castes.	frequency	log10 p
GO:0033120	positive regulation of RNA splicing		0.01%	-2.9883
GO:0031328	positive regulation of cellular biosynthetic process		0.67%	-1.9173
GO:0019217	regulation of fatty acid metabolic process		0.02%	-1.6216
GO:0051254	positive regulation of RNA metabolic process		0.54%	-2.1895
GO:0006376	mRNA splice site selection		0.02%	-1.453
GO:0010628	positive regulation of gene expression		0.65%	-1.5251
GO:1903508	positive regulation of nucleic acid-templated transcription		0.52%	-2.2508
GO:2000144	positive regulation of DNA-templated transcription, initiation		0.02%	-1.6216
GO:0000381	regulation of alternative mRNA splicing, via spliceosome		0.02%	-1.9681
GO:0045944	positive regulation of transcription from RNA polymerase II promoter		0.37%	-1.7727
GO:0000375	RNA splicing, via transesterification reactions		0.32%	-1.341
GO:0000398	mRNA splicing, via spliceosome		0.32%	-1.3576
GO:0010557	positive regulation of macromolecule biosynthetic process		0.63%	-2.0302
GO:0032968	positive regulation of transcription elongation from RNA polymerase II promoter		0.03%	-1.3167
GO:0046889	positive regulation of lipid biosynthetic process		0.02%	-1.6216
GO:0051130	positive regulation of cellular component organization		0.37%	-1.4576
GO:0051173	positive regulation of nitrogen compound metabolic process		0.69%	-1.7037
GO:0050684	regulation of mRNA processing		0.04%	-1.5292
GO:0050685	positive regulation of mRNA processing		0.01%	-1.3816
GO:0040007	growth		0.32%	-1.4681
GO:0098655	cation transmembrane transport		2.29%	-1.8723
GO:0098660	inorganic ion transmembrane transport		2.32%	-1.397
GO:0071229	cellular response to acid chemical		0.07%	-2.8174
GO:0071233	cellular response to leucine		0.00%	-2.3607
GO:0043200	response to amino acid		0.02%	-1.3167
GO:0032526	response to retinoic acid		0.01%	-1.8401

GO:0071417 cellular response to organonitrogen compound	0.09%	-1.5195
GO:0060359 response to ammonium ion	0.02%	-1.3816
GO:0043933 macromolecular complex subunit organization	2.37%	-2.6964
GO:1901360 organic cyclic compound metabolic process	30.32%	-1.7448
GO:0006725 cellular aromatic compound metabolic process	29.63%	-1.9141
GO:0043610 regulation of carbohydrate utilization	0.00%	-1.5589
GO:0045838 positive regulation of membrane potential	0.00%	-1.3816
GO:0042749 regulation of circadian sleep/wake cycle	0.01%	-2.1467
GO:0007623 circadian rhythm	0.06%	-1.3506
GO:0048520 positive regulation of behavior	0.01%	-1.3914
GO:0010841 positive regulation of circadian sleep/wake cycle, wakefulness	0.00%	-1.5589
GO:0022410 circadian sleep/wake cycle process	0.01%	-1.8401
GO:1904000 positive regulation of eating behavior	0.00%	-1.5589
GO:0042789 mRNA transcription from RNA polymerase II promoter	0.00%	-2.6539
GO:0016071 mRNA metabolic process	0.80%	-1.863
GO:0023041 neuronal signal transduction	0.00%	-1.5589
GO:0099003 vesicle-mediated transport in synapse	0.04%	-1.4992
GO:0046483 heterocycle metabolic process	29.66%	-1.7276
GO:0051028 mRNA transport	0.08%	-1.7456
GO:0050657 nucleic acid transport	0.10%	-1.7642
GO:0051236 establishment of RNA localization	0.10%	-1.7642
GO:0034654 nucleobase-containing compound biosynthetic process	14.53%	-1.6971
GO:0051253 negative regulation of RNA metabolic process	0.63%	-1.8416
GO:0045814 negative regulation of gene expression, epigenetic	0.09%	-1.7099
GO:0021553 olfactory nerve development	0.00%	-1.5589
GO:1904056 positive regulation of cholangiocyte proliferation	0.00%	-1.5589
GO:0031668 cellular response to extracellular stimulus	0.44%	-2.6112
GO:0009267 cellular response to starvation	0.09%	-2.203
GO:0032094 response to food	0.01%	-2.3607
GO:0007584 response to nutrient	0.03%	-1.6216

GO:0046928 regulation of neurotransmitter secretion	0.01%	-2.5451
GO:0030072 peptide hormone secretion	0.04%	-1.6178
GO:0061670 evoked neurotransmitter secretion	0.00%	-1.5589
GO:0099643 signal release from synapse	0.04%	-1.7099
GO:0016080 synaptic vesicle targeting	0.00%	-1.8401
GO:0050806 positive regulation of synaptic transmission	0.02%	-1.6178
GO:0050796 regulation of insulin secretion	0.03%	-1.3167
GO:0051590 positive regulation of neurotransmitter transport	0.00%	-1.9784
GO:1903307 positive regulation of regulated secretory pathway	0.01%	-1.6216
GO:0046883 regulation of hormone secretion	0.04%	-1.4766
GO:0017158 regulation of calcium ion-dependent exocytosis	0.02%	-1.453
GO:0060025 regulation of synaptic activity	0.00%	-1.5589
GO:0072553 terminal button organization	0.00%	-1.6216
GO:0002128 tRNA nucleoside ribose methylation	0.01%	-1.5589
GO:0035158 regulation of tube diameter, open tracheal system	0.00%	-1.5589
GO:0000022 mitotic spindle elongation	0.01%	-2.1467
GO:1904594 regulation of termination of RNA polymerase II transcription	0.00%	-1.5589
GO:0034641 cellular nitrogen compound metabolic process	34.14%	-1.3402
GO:1904193 negative regulation of cholangiocyte apoptotic process	0.00%	-1.5589
GO:0009914 hormone transport	0.07%	-1.3543
GO:0030034 microvillar actin bundle assembly	0.00%	-1.5589
GO:0042542 response to hydrogen peroxide	0.03%	-2.1392
GO:1901701 cellular response to oxygen-containing compound	0.35%	-1.3576
GO:0007389 pattern specification process	0.15%	-1.6653
GO:0097309 cap1 mRNA methylation	0.00%	-1.5589
GO:0090702 non-reproductive fruiting body development	0.01%	-1.5589
GO:0031152 aggregation involved in sorocarp development	0.00%	-1.5589
GO:1902474 positive regulation of protein localization to synapse	0.00%	-1.5589
GO:0048752 semicircular canal morphogenesis	0.00%	-1.5589
GO:0035167 larval lymph gland hemopoiesis	0.00%	-1.453

GO:0010890 positive regulation of sequestering of triglyceride	0.00%	-1.5589
GO:0035886 vascular smooth muscle cell differentiation	0.00%	-1.5589
GO:0060999 positive regulation of dendritic spine development	0.00%	-1.8401
GO:006606 protein import into nucleus	0.10%	-2.4091
GO:0006913 nucleocytoplasmic transport	0.24%	-1.8812
GO:0010611 regulation of cardiac muscle hypertrophy	0.01%	-1.723

Supplementary 4.0.9: enriched GO terms for the differentially expressed genes identified in the abdomen tissue between reproductive and sterile workers.

term_ID	description	frequency	log10 p-value
GO:0000003	reproduction	0.77%	-1.9293
GO:0002377	immunoglobulin production	0.02%	-1.75
GO:0016447	somatic recombination of immunoglobulin gene segments	0.01%	-1.3517
GO:0009161	ribonucleoside monophosphate metabolic process	2.27%	-4.8011
GO:0046128	purine ribonucleoside monophosphate metabolic process	2.00%	-1.8216
GO:0009206	purine ribonucleoside triphosphate biosynthetic process	0.49%	-1.6418
GO:0034404	nucleobase-containing small molecule biosynthetic process	1.41%	-2.3195
GO:0009259	ribonucleotide metabolic process	2.75%	-2.3893
GO:0006119	oxidative phosphorylation	0.25%	-1.9451
GO:0009116	nucleoside metabolic process	2.92%	-2.5041
GO:0009124	nucleoside monophosphate biosynthetic process	1.49%	-2.3862
GO:0009126	purine nucleoside monophosphate metabolic process	1.92%	-4.7371
GO:0006163	purine nucleotide metabolic process	2.44%	-2.4425
GO:0009144	purine nucleoside triphosphate metabolic process	1.40%	-3.5224
GO:0009142	nucleoside triphosphate biosynthetic process	0.65%	-1.7311
GO:0009168	purine ribonucleoside monophosphate biosynthetic process	1.04%	-2.7261
GO:0006753	nucleoside phosphate metabolic process	4.21%	-3.223
GO:0046034	ATP metabolic process	1.26%	-2.5418
GO:0015986	ATP synthesis coupled proton transport	0.41%	-1.3517
GO:0009199	ribonucleoside triphosphate metabolic process	1.46%	-3.6311
GO:0010212	response to ionizing radiation	0.04%	-2.0714
GO:0009056	catabolic process	4.82%	-1.8709
GO:0051276	chromosome organization	1.48%	-3.8739
GO:0010605	negative regulation of macromolecule metabolic process	1.17%	-3.4332
GO:1902679	negative regulation of RNA biosynthetic process	0.61%	-3.5167
GO:0031327	negative regulation of cellular biosynthetic process	0.77%	-1.4527

GO:0045934 negative regulation of nucleobase-containing compound metabolic process	0.70%	-3.3137
GO:0045892 negative regulation of transcription, DNA-templated	0.59%	-2.0687
GO:0000122 negative regulation of transcription from RNA polymerase II promoter	0.20%	-1.3903
GO:0001935 endothelial cell proliferation	0.02%	-1.8297
GO:0008285 negative regulation of cell proliferation	0.13%	-1.438
GO:0061351 neural precursor cell proliferation	0.03%	-1.3506
GO:0009108 coenzyme biosynthetic process	1.98%	-1.4521
GO:0051186 cofactor metabolic process	3.99%	-1.8198
GO:1902600 hydrogen ion transmembrane transport	1.02%	-3.0119
GO:0015991 ATP hydrolysis coupled proton transport	0.16%	-1.3517
GO:0018205 peptidyl-lysine modification	0.36%	-1.6909
GO:0007293 germarium-derived egg chamber formation	0.01%	-2.3689
GO:0048515 spermatid differentiation	0.04%	-1.5432
GO:0009566 fertilization	0.04%	-1.5748
GO:0051321 meiotic cell cycle	0.18%	-1.8027
GO:0048232 male gamete generation	0.09%	-1.9447
GO:0051402 neuron apoptotic process	0.04%	-1.3044
GO:0006360 transcription from RNA polymerase I promoter	0.05%	-1.5397
GO:0042440 pigment metabolic process	0.49%	-1.3077

Chapter 5: supplementary

Supplementary 5.0.0: data for each worker sample selected for WGBS along with ovary score, age and colony queen-status.

Colony	Worker ID	Weight (mg)	Ovary Score	Age at Sampling (days)	Born before or after queen
08	78	281	4.0	17	Before
08	76	270	4.0	16	Before
08	75	283	3.0	16	Before
19	blue	198	4.0	16	Before
19	68	306	4.0	16	Before
19	67	223	2.0	16	Before
23	20	266	3.5	17	Before
23	22	326	4.0	16	Before
23	23	312	4.0	16	Before
37	77	339	4.0	17	Before
37	76	291	4.0	16	Before
37	75	285	4.0	16	Before

Supplementary 5.0.1: Quantity and quality values for all extracted samples. 260/280 and 260/230 values were determined using a Nanodrop 2000 and quantity was determined using a Qubit fluorometer.

Sample	Concentration (ng/ μ l)	Final Volume (μ l)	Total DNA (μ g)	260/280	260/230
W08	23.0	50.0	1.2	0.8	1.0
W19	26.6	50.0	1.3	1.8	1.1
W23	26.8	50.0	1.3	1.7	0.9
W37	26.0	50.0	1.3	1.8	1.1
Q08	43.8	50.0	2.2	1.8	1.2
Q19	29.8	50.0	1.5	1.8	1.1
Q23	39.8	50.0	2.0	1.8	1.5
Q37	31.6	50.0	1.6	1.8	1.0
M08	39.6	50.0	2.0	1.8	1.0
M19	37.6	50.0	1.9	1.8	1.2
M23	26.4	50.0	1.3	1.8	1.2
M37	42.4	50.0	2.1	1.8	1.0

Supplementary 5.0.2: Alignment data for each sample against the reference genome (Bter_1.0) using Bismark software. Alignment rate shows the percentage of reads that make a unique alignment. Duplicated sequences represents the percentage of sequences removed as they were identified as PCR duplicates.

Sample	Alignment Rate (%)	Duplicated Sequences (%)	Final Coverage
W08	54.6	36.3	12.0
W19	59.4	37.5	14.2
W23	56.1	38.4	13.5
W37	62.8	35.4	12.1
Q08	60.1	37.1	11.6
Q19	56.3	39.7	16.3
Q23	61.9	37.7	15.8
Q37	62.1	41.1	12.3
M08	64.7	25.6	14.1
M19	61.3	27.3	14.7
M23	60.3	27.7	15.0
M37	61.8	27.2	14.4

Supplementary 5.0.3: methylation percentages calculated by the total number of methylated C's divided by the sum of all methylated and unmethylated C's, times by 100. As the lambda genome is unmethylated a 99.5% bisulfite conversion efficiency is assumed.

Sample	CpG	CHG	CHH	Lambda	Corrected CpG	Corrected CHG	Corrected CHH
	Methylation	Methylation	Methylation	Methylation	Methylation	Methylation	Methylation
M08	0.8	0.5	0.5	0.5	0.3	0	0
M19	0.7	0.5	0.5	0.5	0.2	0	0
M23	0.7	0.5	0.5	0.5	0.2	0	0
M37	0.7	0.5	0.5	0.5	0.2	0	0
Q08	0.7	0.5	0.5	0.5	0.2	0	0
Q19	0.7	0.5	0.5	0.5	0.2	0	0
Q23	0.8	0.5	0.6	0.5	0.3	0	0.1
Q37	0.8	0.5	0.5	0.5	0.3	0	0
W08	0.8	0.5	0.5	0.5	0.3	0	0
W19	0.7	0.5	0.5	0.5	0.2	0	0
W23	0.8	0.5	0.5	0.3	0	0	0
W37	0.8	0.5	0.5	0.3	0	0	0

Supplementary 5.0.4: differentially methylated CpGs located in genes, found between queens and males and the corresponding geneIDs

Supplementary 5.0.6: list of enriched GO terms associated with differentially methylated genes between queens and males, $q < 0.05$.

term_ID	description	frequency	log10 p-value
GO:0006891	intra-Golgi vesicle-mediated transport	0.06%	-2.3271
GO:0036098	male germ-line stem cell population maintenance	0.00%	-2.0132
GO:0019827	stem cell population maintenance	0.04%	-1.6074
GO:0043933	macromolecular complex subunit organization	2.37%	-3.8876
GO:0071704	organic substance metabolic process	58.36%	-2.2068
GO:0007023	post-chaperonin tubulin folding pathway	0.02%	-2.0132
GO:0016032	viral process	0.13%	-2.3362
GO:0044419	interspecies interaction between organisms	0.26%	-2.0298
GO:0044764	multi-organism cellular process	0.33%	-1.9835
GO:0007283	spermatogenesis	0.09%	-1.5221
GO:1902680	positive regulation of RNA biosynthetic process	0.52%	-2.6523
GO:0045935	positive regulation of nucleobase-containing compound metabolic process	0.60%	-2.2441
GO:0045899	positive regulation of RNA polymerase II transcriptional preinitiation complex assembly	0.01%	-1.5655
GO:0045893	positive regulation of transcription, DNA-templated	0.52%	-1.6932
GO:0060260	regulation of transcription initiation from RNA polymerase II promoter	0.02%	-1.4372
GO:2000144	positive regulation of DNA-templated transcription, initiation	0.02%	-1.8195
GO:0009891	positive regulation of biosynthetic process	0.67%	-2.2298
GO:0045944	positive regulation of transcription from RNA polymerase II promoter	0.37%	-1.4712
GO:0006457	protein folding	0.90%	-1.4345
GO:0061351	neural precursor cell proliferation	0.03%	-1.4844
GO:0006807	nitrogen compound metabolic process	38.74%	-1.9465
GO:0044238	primary metabolic process	53.74%	-1.376
GO:0043543	protein acylation	0.20%	-2.2041
GO:0055069	zinc ion homeostasis	0.01%	-1.5655
GO:0034260	negative regulation of GTPase activity	0.01%	-1.5655
GO:0043547	positive regulation of GTPase activity	0.47%	-1.341

GO:0072594 establishment of protein localization to organelle	0.49%	-2.0876
GO:0070727 cellular macromolecule localization	1.56%	-1.4661
GO:0006626 protein targeting to mitochondrion	0.11%	-1.4903
GO:0034502 protein localization to chromosome	0.03%	-1.609
GO:0008104 protein localization	2.63%	-1.7514
GO:0000184 nuclear-transcribed mRNA catabolic process, nonsense-mediated decay	0.03%	-1.6856
GO:0006397 mRNA processing	0.56%	-1.4461
GO:0000375 RNA splicing, via transesterification reactions	0.32%	-1.4782
GO:0000398 mRNA splicing, via spliceosome	0.32%	-1.5164
GO:0071044 histone mRNA catabolic process	0.00%	-1.5655
GO:0009048 dosage compensation by inactivation of X chromosome	0.00%	-2.0132
GO:0009059 macromolecule biosynthetic process	19.55%	-2.4136
GO:0002805 regulation of antimicrobial peptide biosynthetic process	0.00%	-2.0878
GO:0002775 antimicrobial peptide production	0.00%	-1.8195
GO:0006974 cellular response to DNA damage stimulus	2.36%	-1.713
GO:0015833 peptide transport	0.30%	-2.0737
GO:0090277 positive regulation of peptide hormone secretion	0.01%	-1.9193
GO:0006310 DNA recombination	1.64%	-1.5034
GO:0002183 cytoplasmic translational initiation	0.03%	-1.3782
GO:0090502 RNA phosphodiester bond hydrolysis, endonucleolytic	0.50%	-2.2345
GO:0000479 endonucleolytic cleavage of tridstronic rRNA transcript (SSU-rRNA, 5.8S rRNA, LSU-rRNA	0.03%	-1.609
GO:0000469 cleavage involved in rRNA processing	0.05%	-1.4372
GO:0071705 nitrogen compound transport	1.77%	-1.5847
GO:0090305 nucleic acid phosphodiester bond hydrolysis	2.27%	-1.4877
GO:0006368 transcription elongation from RNA polymerase II promoter	0.08%	-2.4078
GO:0032785 negative regulation of DNA-templated transcription, elongation	0.01%	-1.5655
GO:0033135 regulation of peptidyl-serine phosphorylation	0.02%	-1.3782
GO:0044267 cellular protein metabolic process	14.29%	-1.6732
GO:0007362 terminal region determination	0.00%	-1.609
